## **List of Acronyms and Abbreviations**

ACF	HHS's Administration for Children and Families
ASEC	CPS Annual Social and Economic Supplement
BLS	Bureau of Labor Statistics
Btu	British thermal unit
CDD	Cooling Degree Day
CPI	Consumer Price Index
CPS	Current Population Survey
DEA	OCS's Division of Energy Assistance
DOE	U.S. Department of Energy
EIA	DOE's Energy Information Administration
EMEU	EIA's Office of Energy Markets and End Use
FY	Fiscal Year
HDD	Heating Degree Day
HHS	U.S. Department of Health and Human Services
LIEAP	Low Income Energy Assistance Program
LIHEAP	Low Income Home Energy Assistance Program
MMBtus	Million British thermal units
NOAA	National Oceanographic and Atmospheric Administration
OCS	ACF's Office of Community Services
P.L.	Public Law
RECS	Residential Energy Consumption Survey

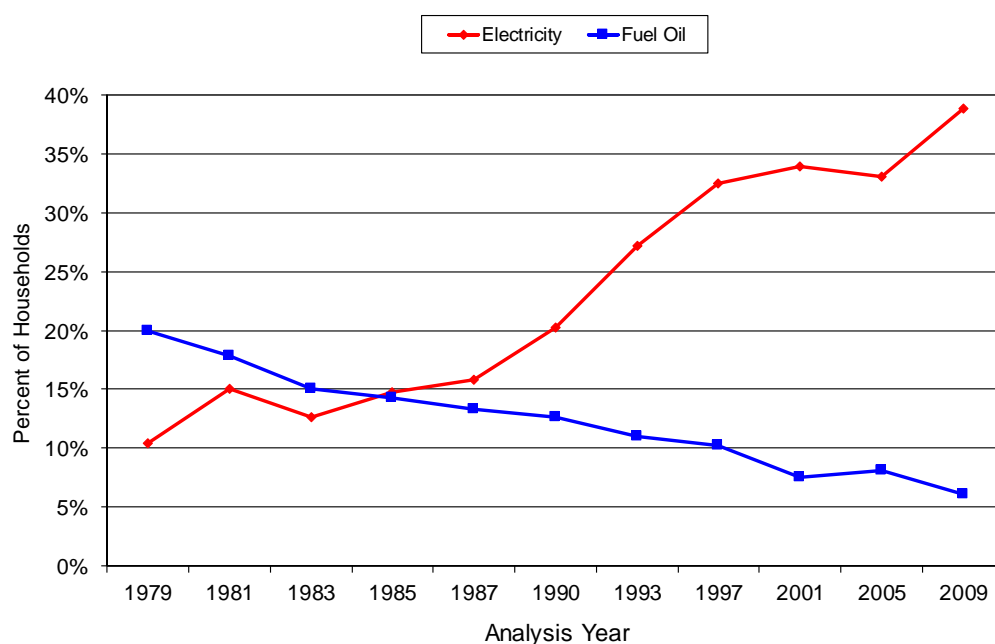

## Executive Summary

This report presents data on home energy trends for low income households from 1979 through 2009 or FY 2017, depending upon the latest year of availability.<sup>1</sup> Statistics are derived from a series of national residential energy consumption surveys (including the Residential Energy Consumption Survey, or RECS) and from the U.S. Department of Health and Human Services' (HHS's) administrative statistics. The analyses show significant shifts since 1979 in the types and amounts of energy used by low income households.

### Home heating and cooling trends

Figure 1 demonstrates that the share of low income households that used electricity as their main heating fuel increased from about 10 percent in 1979 to 34 percent in 2001, dropped slightly to 33 percent in 2005, and increased to almost 39 percent in 2009. In contrast, the share of low income households that used fuel oil as their main heating fuel steadily declined from 20 percent in 1979 to 6 percent in 2009. Natural gas remained the dominant type of space heating fuel used over the 30-year period.

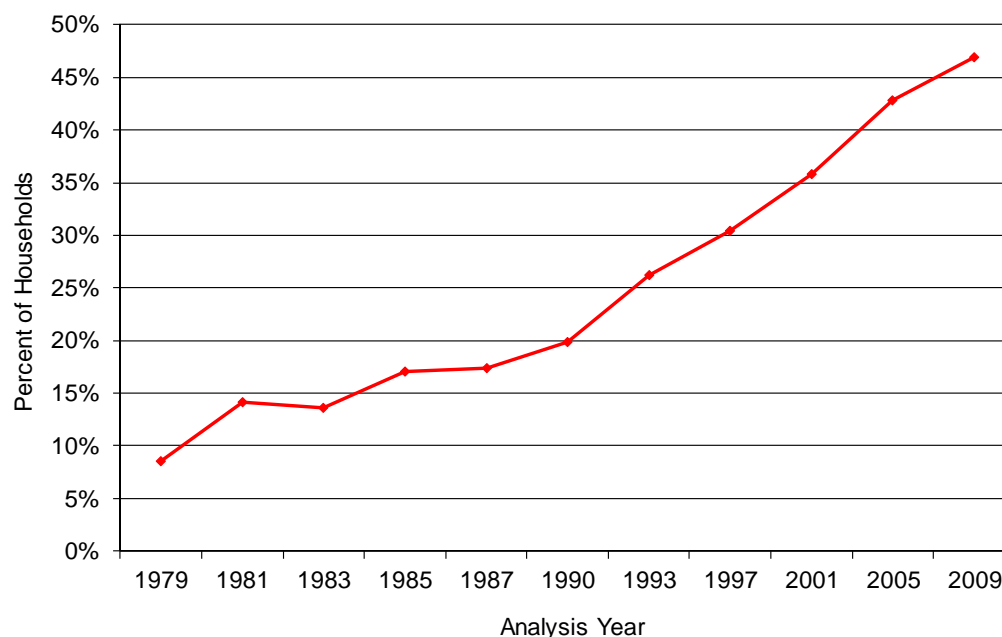

**Figure 1. Percent of low income households using electricity and fuel oil as main heating fuels, 1979 to 2009**

As shown in Figure 2, the most important change in home cooling on the part of low income households has been in the percentage of households with central air-conditioning. The share of low income households who use central air-conditioning increased from 8.5 percent in 1979 to almost 47 percent in 2009.

<sup>1</sup> In this report, low income households are defined as those households with incomes at or below 150 percent of HHS Poverty Guidelines.

**Figure 2. Percent of low income households using central air-conditioning, 1979 to 2009**

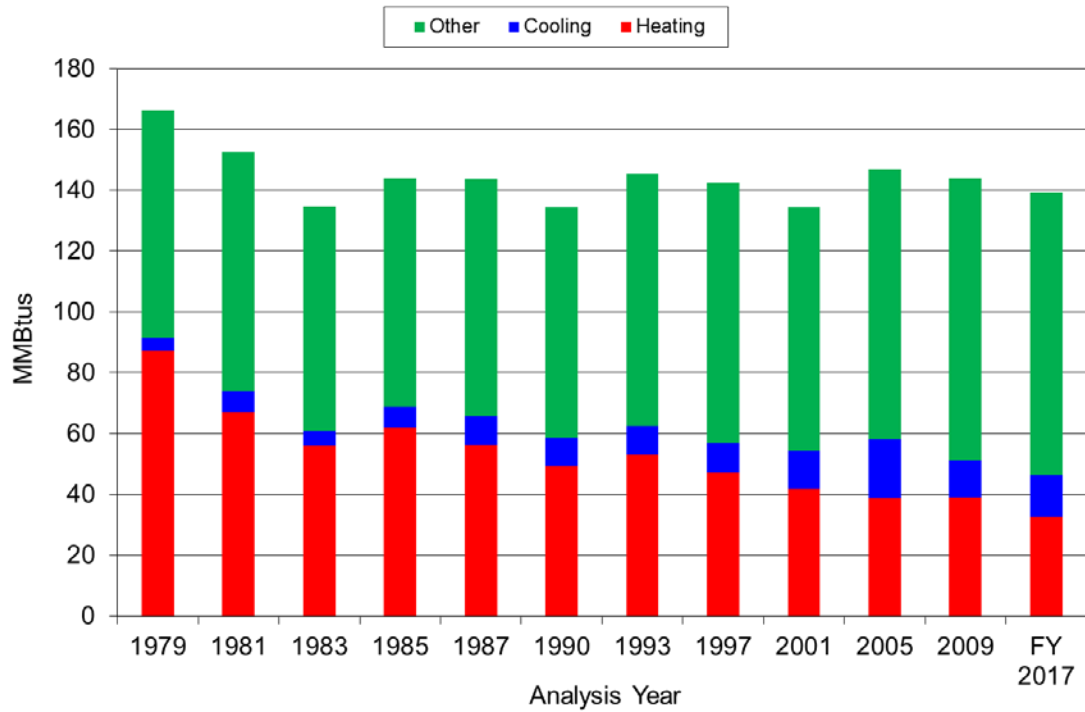

### **Trends in mean residential consumption, expenditures, and energy burden**

Low income households substantially decreased their mean residential energy consumption between 1979 and 1983, as shown in Figure 3. This suggests a significant increase in efficiency resulting from conservation measures or actions. From 1983 to 1990, mean residential energy consumption fluctuated from year to year, corresponding to expected changes in heating and cooling consumption because of changes in heating and cooling degree days. For 1993 through 2005, there appears to have been an increase in the use of energy for purposes other than home heating and home cooling. Between 2005 and 2009, the decrease in home cooling was slightly offset by higher consumption for purposes other than home cooling or heating. Between 2009 and FY 2017, there was a slight decrease in home heating and a slight increase in home cooling consumption.

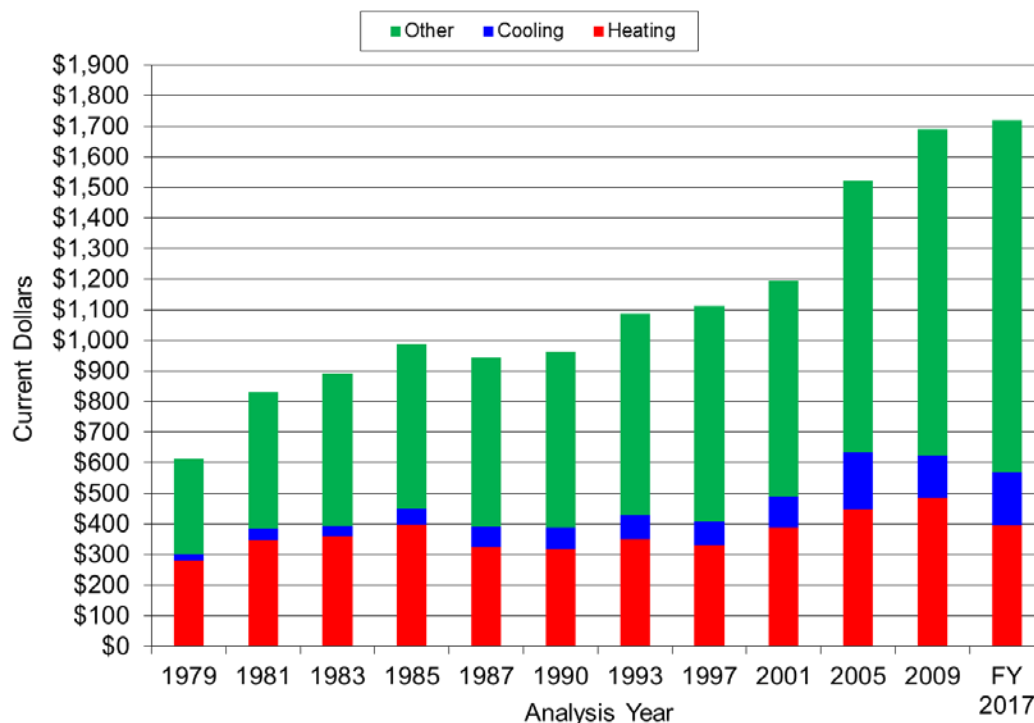

**Figure 3. Mean residential energy consumption (in MMBtus) per low income household, 1979 to FY 2017<sup>1</sup>**

<sup>1</sup> A British thermal unit (Btu) is the amount of energy necessary to raise the temperature of one pound of water one degree Fahrenheit. MMBtus refer to values in millions of Btus.

Mean residential energy expenditures increased rapidly between 1979 and 1985 because of fuel price increases, as shown in Figure 4. From 1987 through 1997, these expenditures rose moderately; however, from 2001 through 2009, mean expenditures on heating increased steadily as the result of fuel price increases and colder winter weather. Between 2009 and FY 2017, mean expenditures for home heating decreased, due to the low number of heating degree days in FY 2017. Mean expenditures on uses other than home heating or home cooling rose continuously from 1979 to FY 2017. Mean expenditures on cooling rose from 1979 to 2005. In 2009, expenditures on cooling decreased relative to 2005 but expenditures on heating and for other purposes increased. Between 2009 and FY 2017, mean expenditures on home heating decreased, but expenditures on home cooling and for other purposes increased.

**Figure 4. Mean residential energy expenditures for low income households, 1979 to FY 2017**

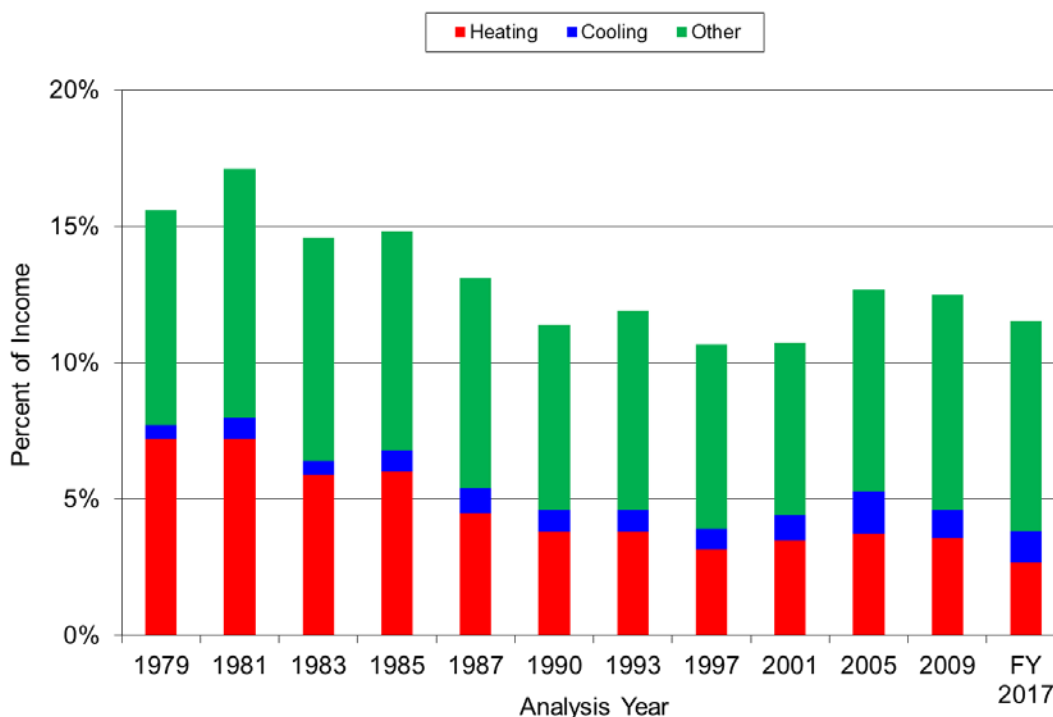

As Figure 5 shows, the mean group home energy burden (i.e., burden associated with home heating and home cooling) declined from 7.7 percent in 1979 to 3.9 percent in FY 2017; a decrease of 3.8 percentage points.<sup>2</sup> The decrease in mean group residential energy burden from 1979 to FY 2017 was 4.0 percentage points (from 15.6 percent to 11.6 percent). Most of the decrease in residential energy burden is associated with a decrease in home energy burden rather than a decrease in the burden associated with energy use for other purposes (i.e., water heating, appliances, and refrigeration).

---

<sup>2</sup> Mean group burden is defined in Appendix A.

**Figure 5. Mean group residential energy burden by end use for households with incomes at or below 150 percent of HHS Poverty Guidelines, 1979 to FY 2017**

### **Analysis of fuel price and energy efficiency trends**

Trends in energy consumption and expenditures are dependent on factors such as energy prices, weather, and energy efficiency. Fuel prices outpaced the Consumer Price Index (CPI) from 1979 through 1983, as shown in Figure 6 on the next page. While the CPI increased about 37 percent, the composite average of fuel prices (a weighted average of electric, natural gas, and fuel oil prices) increased by about 81 percent between 1979 and 1983. From 1985 through 1993, fuel prices rose at a slower rate than did the CPI (i.e., at a slower rate than the cost of other goods). From 1997 to through 2009, however, fuel prices rose at a higher rate than did the prices of other goods. In FY 2017, the composite energy price index was 399 and the CPI was 336. Relative to 2009, the CPI in FY 2017 increased at a faster rate than the composite energy price index. In FY 2017, the composite energy price index increased by about 8 percent relative to 2009, whereas the CPI increased by about 15 percent.

The impact of energy prices on energy expenditures resulted in low income household energy expenditures surging upward until 1985 even though energy consumption for these households declined over the same period. The 19 percent growth in composite fuel prices from 1985 to 1997 explains why residential energy expenditures per low income household rose slightly during that period. In 2001, fuel prices increased by 17 percent over 1997 prices; 2005 fuel prices increased by 24 percent over 2001 prices; and 2009 fuel prices increased by nearly 15 percent over 2005 prices. In FY 2017, fuel prices increased again and were about 8 percent higher than 2009 fuel prices. The increases in fuel prices from 2009 through FY 2017 contributed to the rise in expenditures during that period.

**Figure 6. Shifts in composite energy price index and Consumer Price Index (CPI), 1979 to FY 2017**

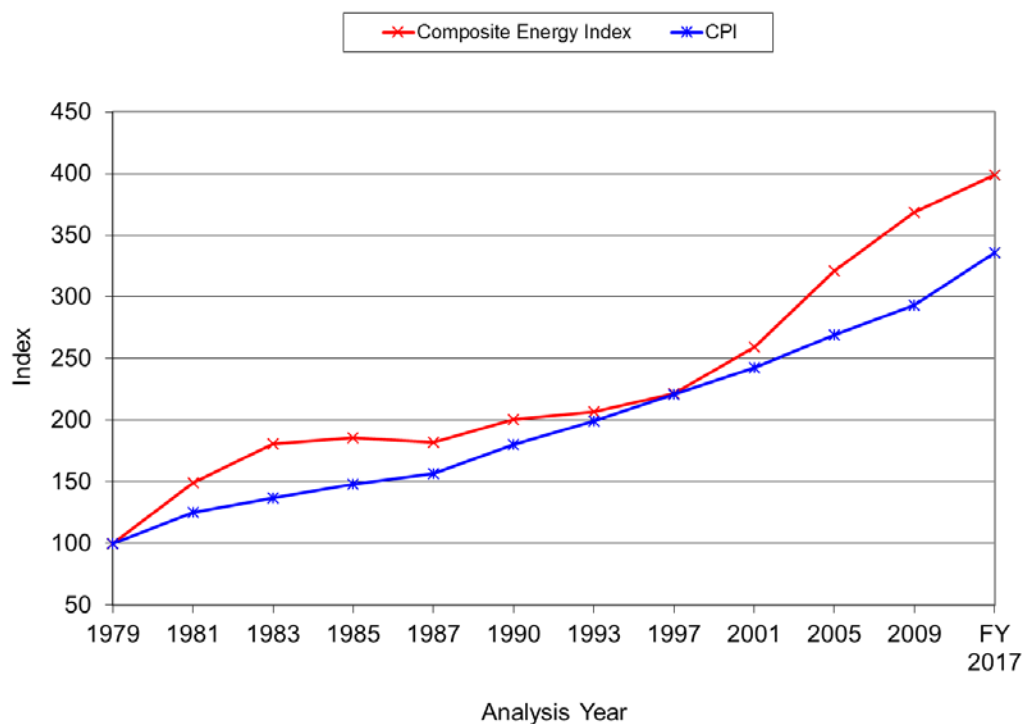

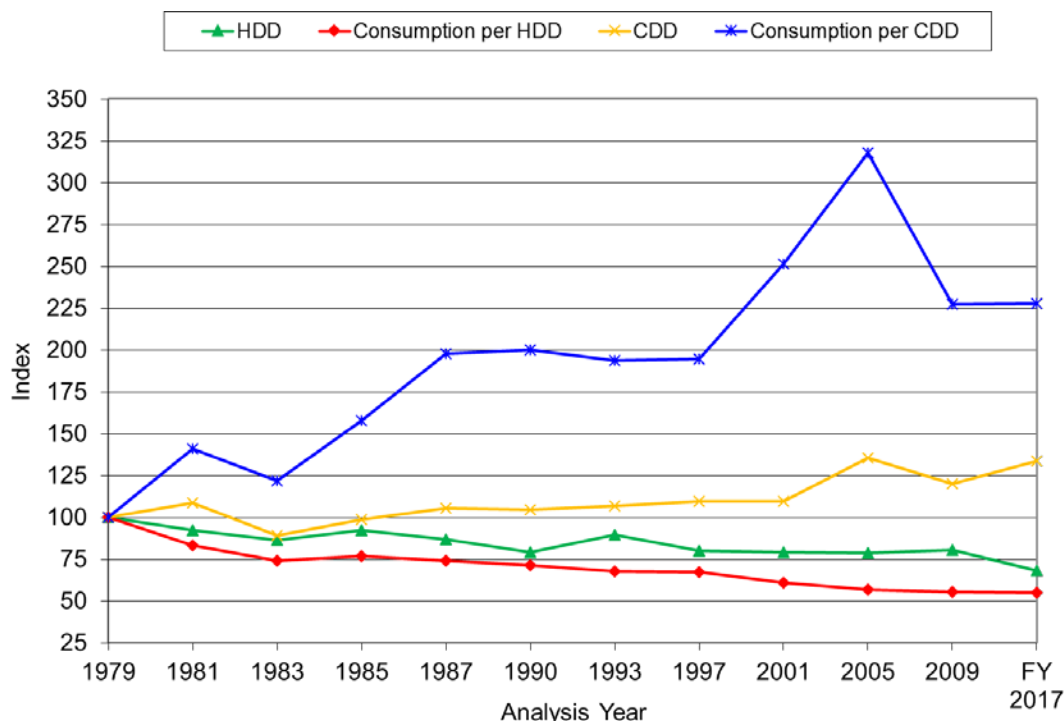

Figure 7 shows on the next page average energy consumption for heating and cooling compared to heating and cooling degree days from 1979 to FY 2017 for low income households. As shown, heating consumption per heating degree day generally declined from 1979 to FY 2017 probably at least in large part due to energy conservation efforts. In contrast, cooling consumption per cooling degree day rose through FY 2017, with a spike around 2001 and 2005, because of a large increase in the availability of air-conditioning to low income households.<sup>3</sup> Only 37 percent of low income households had air-conditioning equipment in 1979, but by 2005 the number had risen to 80 percent, followed by a slight decrease in 2009 to 77 percent.

---

<sup>3</sup> Air-conditioning equipment includes central air conditioners and window or wall units, ceiling fans, and evaporative coolers. The availability of all household appliances increased for low income households over this period due to the overall increase in the wealth of the nation and to the decrease in the cost of older technologies.

**Figure 7. Index of heating degree days (HDD), average heating consumption for low income households per HDD, cooling degree days (CDD), and average cooling consumption for low income households per CDD, 1979 to FY 2017**

The mean group home energy burden for low income households has remained considerably higher than the burden for all households. In 1979, the mean group home energy burden was 7.7 percent for low income households, while the mean group home energy burden for all households was 1.9 percent. In FY 2017, the mean group home energy burden for all households was 0.9 percent, while the mean group home energy burden for low income households was 3.8 percent. Again, this is more than four times higher than that for all households.

## Trends in LIHEAP

Between 1981 and FY 2017, as shown in Figure 8, the number of income eligible households has risen by about 83 percent, during which time federal fuel assistance funds have increased by about 67 percent.<sup>4</sup> Also during this period, the percentage of income eligible households receiving heating and/or winter crisis assistance has declined from 36 percent in 1981 to 15 percent in FY 2017 – though this figure has remained reasonably steady since 1997.<sup>5</sup> Before adjusting for inflation, average winter crisis and heating benefits per household increased until 1985, fell in 1987, stayed in the same range through 1997, increased significantly in 2001, dropped by over 16 percent in 2005, rose by nearly 66 percent in 2009, and then decreased by about 14 percent FY 2017. Cooling benefits per household actually fell until 1985 and increased sharply from 1993 through 2001, and then fell by over 6 percent in 2005, rose nearly 77 percent in 2009, and then decreased by about 11 percent in FY 2017. After adjusting for inflation, the mean value

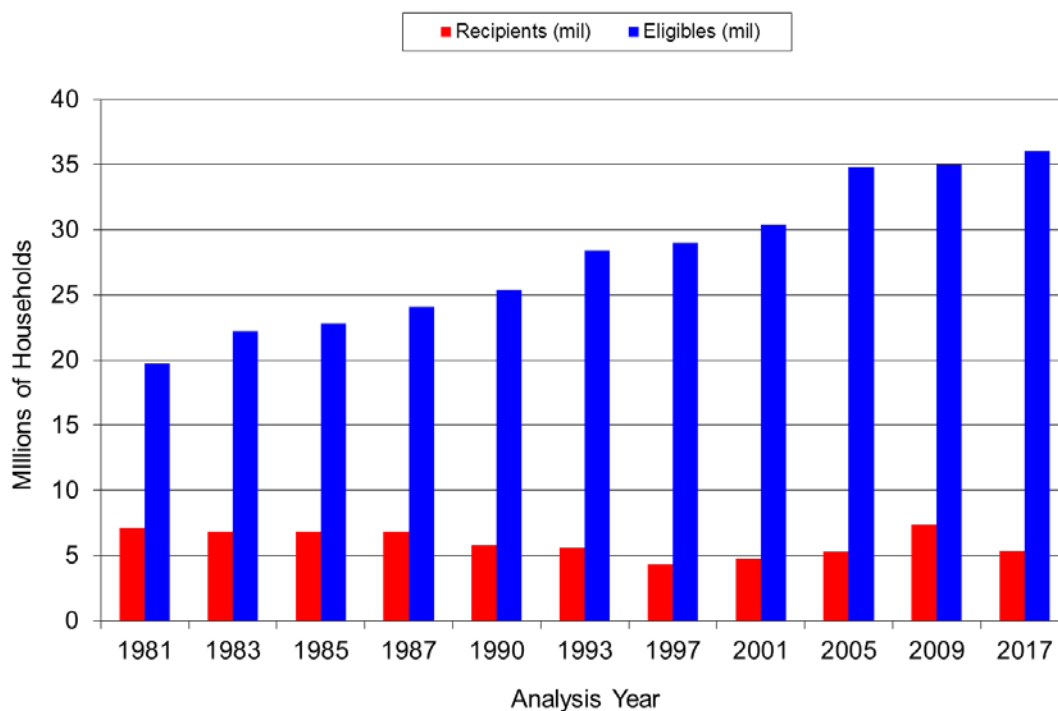

<sup>4</sup> Income eligible household estimates do not include those households with incomes greater than the statutory income standards but who may still qualify for LIHEAP benefits because they are categorically eligible for LIHEAP under section 8624 (b)(2)(A) of the LIHEAP statute.

<sup>5</sup> Note that The FY 1981 estimate of income eligible households are not directly comparable to those of the other years because the income eligibility guidelines for the FY 1981 program differed from those of other years.

of combined federal heating and winter crisis benefits fell (in 1981 dollars) from \$213 in 1981 to \$158 in FY 2017. Cooling benefits decreased (in 1981 dollars) from \$129 in 1981 to \$114 in FY 2017.

The percentage of the total home heating bill for Low Income Energy Assistance Program/Low Income Home Energy Assistance Program (LIEAP/LIHEAP) income eligible households covered by LIEAP/LIHEAP heating and winter crisis benefits decreased from 23 percent in 1981 to 15 percent in FY 2017. The decrease resulted from the combination of higher home heating bills and an increase in the size of income eligible population.

**Figure 8. Number of LIEAP/LIHEAP income eligible and heating and/or winter crisis assistance recipient households, FY 1981 to FY 2017**

The mean group home heating burden for LIEAP/LIHEAP assisted households is substantially reduced because of the LIHEAP benefits. In FY 2017, the net mean group home heating burden for LIHEAP assisted households was 0.8%. However, it has historically been about twice the burden of all households, even with the assistance.

## **I. Introduction**

The Administration for Children and Families (ACF) within the U.S. Department of Health and Human Services (HHS) administers at the federal level the Low Income Home Energy Assistance Program (LIHEAP). ACF awards annual LIHEAP block grants to assist eligible low income households in meeting their home energy costs. ACF issues such grants to the 50 states and the District of Columbia, certain Indian tribes and tribal organizations, and certain U.S. insular areas.

In 1994, Congress amended the purpose of LIHEAP to clarify that LIHEAP is “to assist low income households, particularly those with the lowest incomes, that pay a high proportion of household income for home energy, primarily in meeting their immediate home energy needs” (The Human Services Amendments of 1994, Public Law (P.L.) 103-252, Sec. 302). Congress further indicated that LIHEAP grantees need to reassess their LIHEAP benefit structures to ensure that they are actually targeting those low income households that have the highest energy costs or needs. The Energy Policy Act of 2005 (P.L. 109-58) reauthorized LIHEAP through FY 2007 without substantive changes. LIHEAP’s reauthorization is currently pending.

For LIHEAP grantees to reassess their LIHEAP benefit structures, they need performance statistics on LIHEAP applicants and eligible households. In addition, they need technical assistance in how to make use of the performance statistics in planning and implementing changes to their programs.

The *Low Income Home Energy Trends Report* focuses on the home energy mission of LIHEAP by furnishing data and analyses on low income home energy trends for the period from 1979 to FY 2017. Subsections include trends in consumption, expenditures, and burden; analysis of energy price and energy efficiency trends; trends in LIHEAP; and analysis of LIHEAP benefits. Previously, the *Low Income Home Energy Trends Report* was published as part of the *LIHEAP Home Energy Notebook*, which included additional sections on the latest national and regional data on home energy consumption, expenditures, and burden; characteristics of the low income population in each state; federal LIHEAP targeting performance; and special studies of important issues related to LIHEAP and low income home energy needs. Beginning with data for FY 2015, the individual sections of the *LIHEAP Home Energy Notebook* have been published separately in an effort to make the data available to LIHEAP grantees in a more timely fashion.

The FY 2017 home energy data presented in this report were derived from existing data sources and analytic procedures. These include the following:

- For household-level data on home energy: the national Residential Energy Consumption Surveys (RECS) for 2009, which is administered by the Department of Energy (DOE), Energy Information Administration (EIA).
- For household-level data on income: the national Current Population Survey’s (CPS’s) Annual Social and Economic Supplement (ASEC), which is administered by the Department of Commerce, Bureau of the Census (Census).
- For national- and state-level data on residential energy prices: EIA’s publication *Monthly Energy Review* for electricity price, natural gas price and consumption, and fuel oil/kerosene and liquefied petroleum gas (LPG) consumption; EIA’s publication *Electric Power Monthly* for electricity consumption; EIA website for LPG price; and the Bureau of Labor Statistics (BLS) Consumer Price Index for fuel oil/kerosene price.
- Other publicly available sources of data such as weather data from the Department of Commerce, National Oceanographic and Atmospheric Administration (NOAA).

## ***Low Income Home Energy Trends for FY 2017: I. Introduction***

---

- End use disaggregation procedures developed by EIA's Office of Energy Markets and End Use (EMEU).
- Data on states' expenditure of funds by component and numbers of households served by type: Office of Community Services (OCS) Division of Energy Assistance's (DEA's) administrative data from the *LIHEAP Household Report for Federal Fiscal Year (FFY) 2017* and the *LIHEAP Performance Data Form for Federal Fiscal Year (FFY) 2017*.<sup>6</sup>

---

<sup>6</sup> Starting in FY 2015, the *LIHEAP Grantee Survey* was incorporated into the *LIHEAP Performance Data Form* (OMB Control No. 0970-0449).

## **II. Low Income Home Energy Trends**

Important shifts in energy prices and consumption have occurred since the 1973 oil embargo. As a result, the energy expenditures and energy burdens of low income households have changed significantly.

In the *LIHEAP Report to Congress for FY 1989*, Appendix K presented the results of a national study of residential energy consumption, expenditures, and burden for low income households from 1973 to 1989. Selected tables from that study were updated and published as a regular appendix in annual LIHEAP reports to Congress for FY 1991 through FY 1996. Beginning with the FY 1997-FY 1999 report, the tables are only published in the annual *LIHEAP Home Energy Notebook*. The tables present data for low income households and, for comparison purposes, include statistics on all households. Beginning with 1979, the year before HHS's first energy assistance program was enacted, trend data are furnished on the following:

- Home energy consumption, expenditures, and burden.
- Factors affecting consumption, expenditures, and burden.
- The impact of LIHEAP assistance on net home energy expenditures.

A number of special terms are used throughout this report. Table 2-1 on the next page defines these special terms. One such term is “low income,” which is defined as having income at or below 150 percent of HHS Poverty Guidelines. Because of limitations on the availability of data, this definition is more restrictive than that used in the other reports comprising the *Notebook*. In those reports, “low income” refers to LIHEAP income eligible households, which are households that would be income-eligible for LIHEAP if their states set the income-eligibility guidelines at the federal maximum (the greater of 150 percent of HHS Poverty Guidelines or 60 percent of the state median income). Based on estimates from the 2017 CPS ASEC, the definition based solely on 150 percent of HHS Poverty Guidelines excludes about 10.5 million households of the 36.0 million households that meet the definition of LIHEAP income eligible households. Therefore, differences in FY 2017 home energy data included in this report and that included in the other comprising the *Notebook* are the result of the difference in the definition of “low income.”<sup>7</sup> Unless indicated otherwise, the energy data in this report are based on eleven national residential energy surveys of occupied residential housing units and their fuel suppliers. Table 2-2 identifies the surveys used, the date on which household interviews began, the time period in which residential energy bills were collected from fuel suppliers, the time frame for household income, and the number of households included in the survey.

For each survey, a national sample of residential housing units was selected, and interviewers attempted personal contacts with the householder. For those housing units where an authorization form was completed, the household's fuel supplier was contacted and asked to supply fuel costs and consumption data.

The collection of income data is not a primary focus of the residential energy surveys. Income statistics from the CPS ASEC are used to improve income data.

---

<sup>7</sup> As noted in Table 2-2, the data files used in this study include surveys from 1979 and 1981. The variable that designates LIHEAP income eligibility was not coded for those data files.

## ***Low Income Home Energy Trends for FY 2017: II. Low income Home Energy Trends***

**Table 2-1. Definition of special terms**

Term	Definition
Billing data	Energy cost and consumption data furnished by the household's fuel supplier.
Composite price	The weighted average price of electricity, natural gas, and fuel oil used for residential purposes.
Real dollar expenditures	Costs adjusted for changes in the price of a market basket of consumer goods between two years (i.e., adjusted for inflation or deflation).
Cooling degree days	Daily cooling degree days are computed by subtracting a base temperature (65 degrees Fahrenheit) from a day's mean temperature when it exceeds 65 degrees Fahrenheit. If the mean temperature on a day is 70, the number of cooling degree days experienced on that day is 5 (70 minus 65). In this <i>Notebook</i> , we refer to annual cooling degree days, or the sum of all cooling degree days experienced during a year.
(Nominal) Dollar expenditures	Actual costs as reported in the year of the energy survey (unadjusted for inflation or deflation). Unless noted otherwise all dollar expenditures are unadjusted.
Energy burden	The share or percentage of annual household income that is used to pay annual energy bills. <sup>1</sup>
Energy end uses	The specific use of energy in the home for home heating, home cooling or ventilation, water heating, and appliances.
Fuel assistance	LIHEAP heating, cooling, and crisis assistance.
Heating degree days	Daily heating degree days are computed by subtracting the mean temperature for a day, when that temperature falls below 65 degrees Fahrenheit, from a base temperature (65 degrees Fahrenheit). For example, if the mean temperature on a day is 60 and the base temperature is 65, the number of heating degree days experienced on that day is 5 (65 minus 60). In this <i>Notebook</i> , we refer to annual heating degree days, or the sum of all heating degree days experienced during a year.
Home energy expenditures	Expenditures for home space heating and home space cooling.
LIHEAP burden offset	The reduction in mean group home heating burden as a result of LIHEAP benefits
LIHEAP coverage rate	The percentage of the aggregate home energy bills for low income households that is covered by LIHEAP fuel assistance.
LIHEAP income eligible households	Households with incomes at or below the federal maximum LIHEAP income standard – at or below the greater of 150 percent of HHS Poverty Guidelines or 60 percent of the state median income.
LIHEAP participation rate	The percentage of LIHEAP income eligible households that receive fuel assistance.
LIHEAP recipient households	Households that indicated receiving home heating, cooling, or energy crisis benefits during the 12 months prior to a particular household survey.
Low income households	Households with incomes at or below 150 percent of HHS Poverty Guidelines.
Mean	The mean is the sum of all values divided by the number of values, or what is commonly called the average
Median	The median is the value at the midpoint in the distribution of values
MMBtus	A British thermal unit (Btu) is the amount of energy necessary to raise the temperature of one pound of water one degree Fahrenheit. MMBtus refers to millions of Btus. An average household uses about 100 MMBtus per year.
Residential energy expenditures	Fuel expenditures for all residential uses, including home heating, home cooling or ventilation, water heating, refrigeration, clothes drying, etc.

<sup>1</sup> Three different energy burden statistics are used in this report: mean group burden, mean individual burden, and median individual burden. The definitions of these statistics are presented preceding Figure 2-5.

## **Low Income Home Energy Trends for FY 2017: II. Low income Home Energy Trends**

Table 2-2 presents information on the series of surveys that were used to prepare this *Notebook*. The reader should note that the in-home interview dates lag behind the analysis year for the years 1979 through 1985. In those years, the energy supplier survey included data from the year following the in-home interview. In all cases, the analysis year coincides with the end of the energy consumption history.

**Table 2-2. Data used for the study of low income home energy trends**

Analysis Year <sup>1</sup>	1979	1981	1983	1985	1987	1990	1993	1997	2001	2005	2009	FY 2017

<sup>2</sup> Surveys include the National Interim Energy Consumption Survey (NIECS) and the RECS.

<sup>3</sup> Month and year in which household interviews began.

<sup>4</sup> Data projected from the 2009 RECS using changes in weather and prices. See Appendix A for the procedure used to calculate the projections.

<sup>5</sup> Time period in which residential energy bills were collected from fuel suppliers.

<sup>6</sup> Mean income computed using calendar year data from the CPS ASEC.

### **Trends in energy use, consumption, expenditures, and burden**

Since 1979, there have been important changes in the fuels used by households, the amount of energy consumed for specific residential end uses (i.e., home heating, water heating, home cooling, and for other appliances), total residential energy expenditures, and the burden that residential energy expenditures represent for low income households. This section presents data that illustrate these changes.

Figures 2-1 and 2-2, on the next page, furnish information on the fuel choices by low income households. Figure 2-1 shows that low income households have increased their use of electricity as a main heating fuel, from 10.4 percent in 1979 to 38.9 percent in 2009, while they have reduced their use of fuel oil or kerosene as a main heating fuel, from 20.0 percent in 1979 to 6.0 percent in 2009.<sup>8</sup> In addition, the use of wood or coal as a main heating fuel (included under “Other”) peaked in 1985, declined substantially through 2001, almost doubled by 2005, and fell to 3.1 percent in 2009.

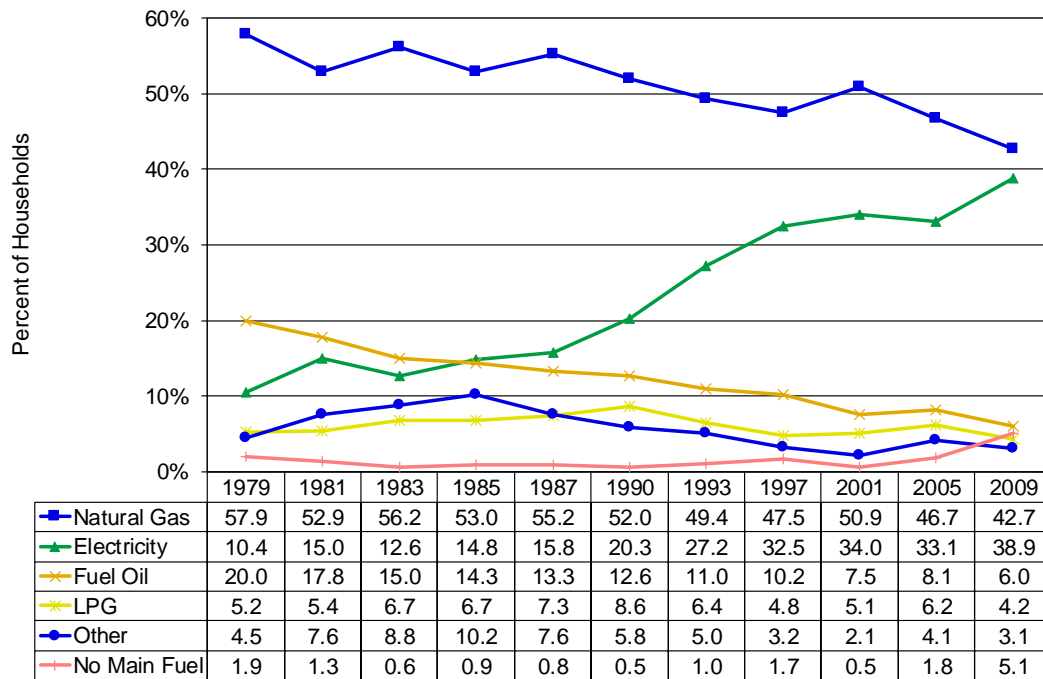

Figure 2-2 shows that low income households increased their use of central air-conditioning systems from 8.5 percent in 1979 to 46.9 percent in 2009.<sup>9</sup> The proportion of low income households with no air-conditioning fell from 62.8 percent in 1979 to 22.7 percent in 2009. Other things being equal, increased use of air-conditioning equipment among low income households can be expected to increase home cooling expenditures.

<sup>8</sup> For all households, the share using electricity as their main heating fuel grew from 15.8 percent in 1979 to 33.6 percent in 2009, and the share using fuel oil or kerosene as their main heat fell from 22.1 percent to 6.5 percent.

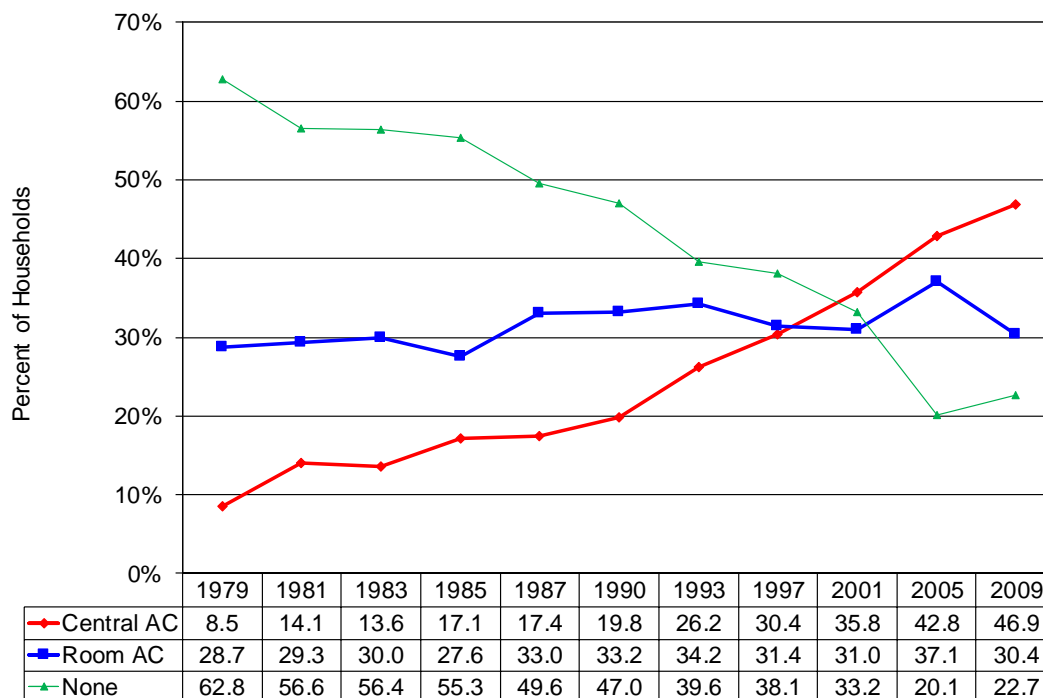

<sup>9</sup> For all households, the share using electric central air-conditioning grew from 23 percent in 1979 to 61 percent in 2009.

## Low Income Home Energy Trends for FY 2017: II. Low Income Home Energy Trends

**Figure 2-1. Main heating fuel for households with incomes at or below 150 percent of HHS Poverty Guidelines, 1979 to 2009**

**Figure 2-2. Air-conditioning type for households with incomes at or below 150 percent of HHS Poverty Guidelines, 1979 to 2009**

## Low Income Home Energy Trends for FY 2017: II. Low Income Home Energy Trends

Figures 2-3 and 2-4 furnish information on the trends in mean residential energy consumption and expenditures for low income households from 1979 to FY 2017. Figure 2-3 shows that low income households substantially reduced their residential energy consumption between 1979 and 1983. This suggests a significant increase in efficiency resulting from conservation measures or actions. Examination of the components of residential energy consumption indicates that the reduction was the result of reductions in home heating consumption. From 1983 to 1990, mean residential energy consumption fluctuated from year to year, corresponding to expected changes in heating and cooling consumption that resulted from changes in heating and cooling degree days.<sup>10</sup> For 1993 through 1997, there appears to have been a significant increase in the use of energy for purposes other than home heating and home cooling. In 2001, the use of energy for purposes other than heating and cooling dropped but then increased until 2009.

**Figure 2-3. Mean residential energy consumption per household in MMBtus by end use for households with incomes at or below 150 percent of HHS Poverty Guidelines, 1979 to FY 2017**

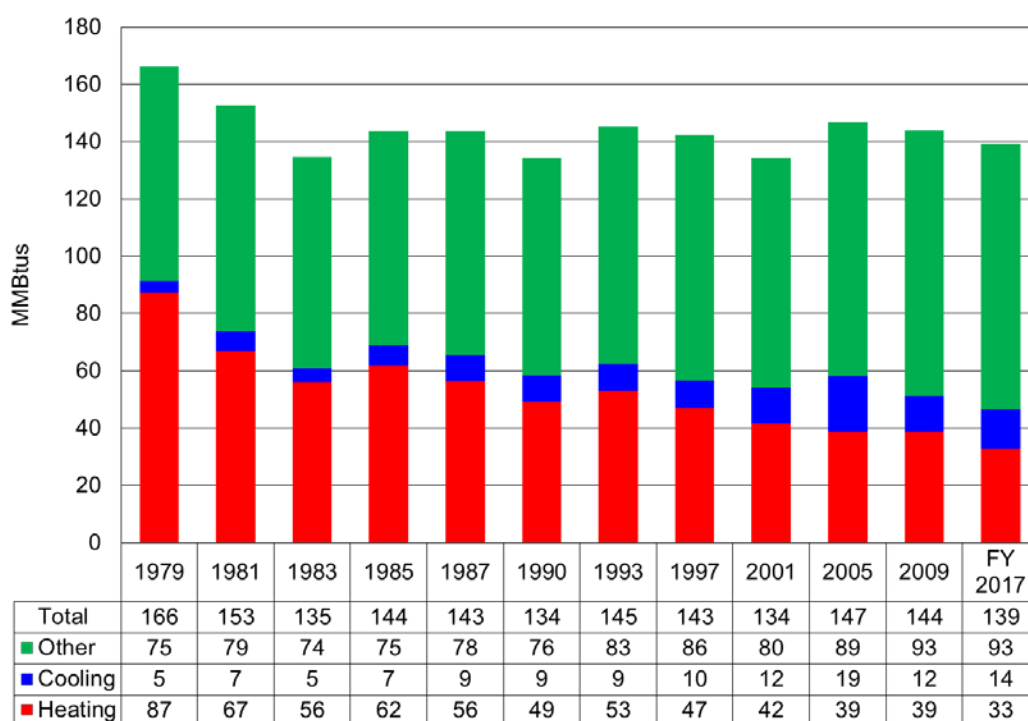

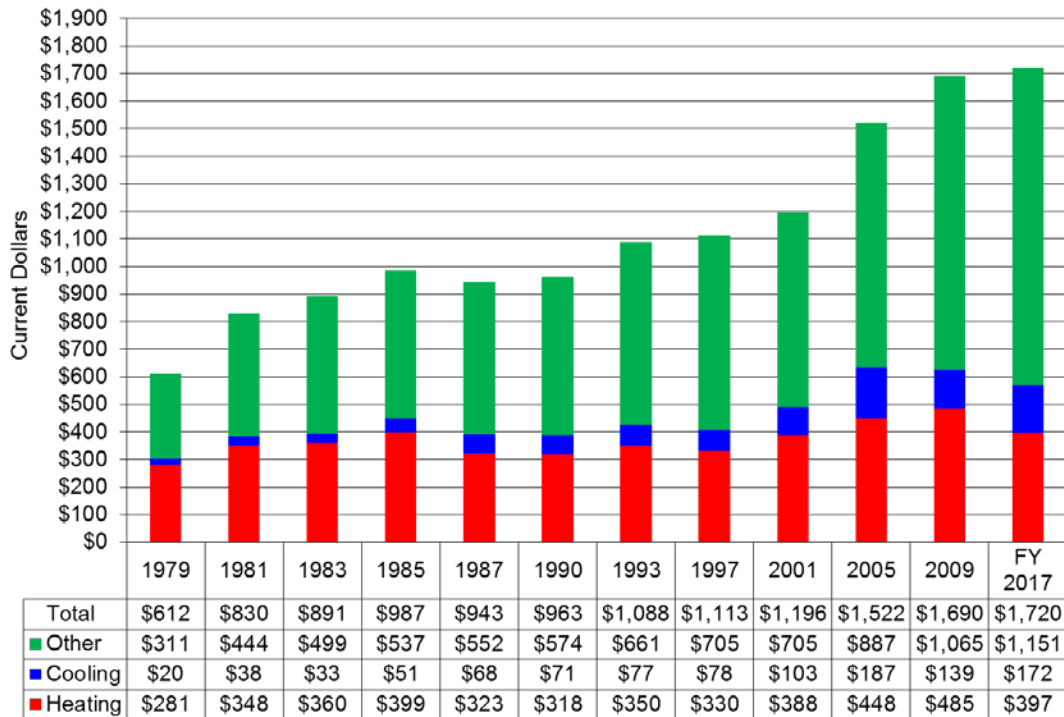

Figure 2-4, on the next page, shows that mean residential energy expenditures for low income households increased rapidly from 1979 to 1985; the increases were the result of fuel price increases. Examination of the components of energy expenditures indicates that the greatest increases were in home cooling and other residential expenditures, while increases in home heating expenditures were more moderate until a spike in 2009. Mean residential energy expenditures increased at a moderate rate from \$943 in 1987 to \$1,196 in 2001. From 2001 to 2005, mean residential energy expenditures increased by 27 percent to \$1,522, and from 2005 to 2009, mean residential energy expenditures increased by 11 percent to \$1,690. In FY 2017, mean residential energy expenditures were \$1,720, about 2 percent higher than in 2009. Mean home heating expenditures fell from \$399 in 1985 to \$318 in 1990, then rose and fell moderately until 1997. Home heating expenditures saw an 18 percent increase in 2001 over 1997, a 15 percent increase in 2005 over

<sup>10</sup> The numbers presented in this table are not directly comparable to the statistics that appear in Appendix A of the Low Income Home Energy Data report for FY 2016. In this figure, electricity Btus have been adjusted to be comparable to Btus for other fuels. This adjustment procedure is used to account for Btus lost in the generation and transmission of electricity to the housing unit and to thereby furnish a better picture of changes in energy efficiency over time.

## Low Income Home Energy Trends for FY 2017: II. Low Income Home Energy Trends

2001, and about an 8 percent increase in 2009 over 2005. In FY 2017, home heating expenditures were \$397 – about \$88 lower than in 2009. This decrease was a result of a warm winter, despite a slight increase in energy prices overall. Mean home cooling expenditures rose continuously from \$51 in 1985 to \$187 in 2005. In 2009, mean home cooling expenditures fell to \$139, followed by an increase to \$172 in FY 2017.

**Figure 2-4. Mean residential energy expenditures by end use for households with incomes at or below 150 percent of HHS Poverty Guidelines, 1979 to FY 2017**

The next series of Figures, 2-5 through 2-7, furnishes information on energy burden for low income households.<sup>11</sup> Three different energy burden summary statistics are presented in the three figures: mean group energy burden, mean individual energy burden, and median individual energy burden. Each of the statistics offers somewhat different information and gives somewhat different results. All three are valid from a statistical perspective. The statistics are defined as follows.

- **Mean Group Burden:** Computed as the ratio between mean energy expenditures and mean income for a given set of households, such as low income households. Energy expenditures are computed from RECS and income is derived from the CPS ASEC.
- **Mean Individual Burden:** Computed by finding, using the RECS data, the energy burden for each individual household in a given set (such as low income households) and then taking the mean of these energy burdens for all households in that set.

<sup>11</sup> These figures present gross burden statistics; they do not present net burden statistics, which account for the reduction in burden attributable to the receipt of LIHEAP benefits. Figure 2-26 compares gross burden and net burden for LIHEAP recipient households.

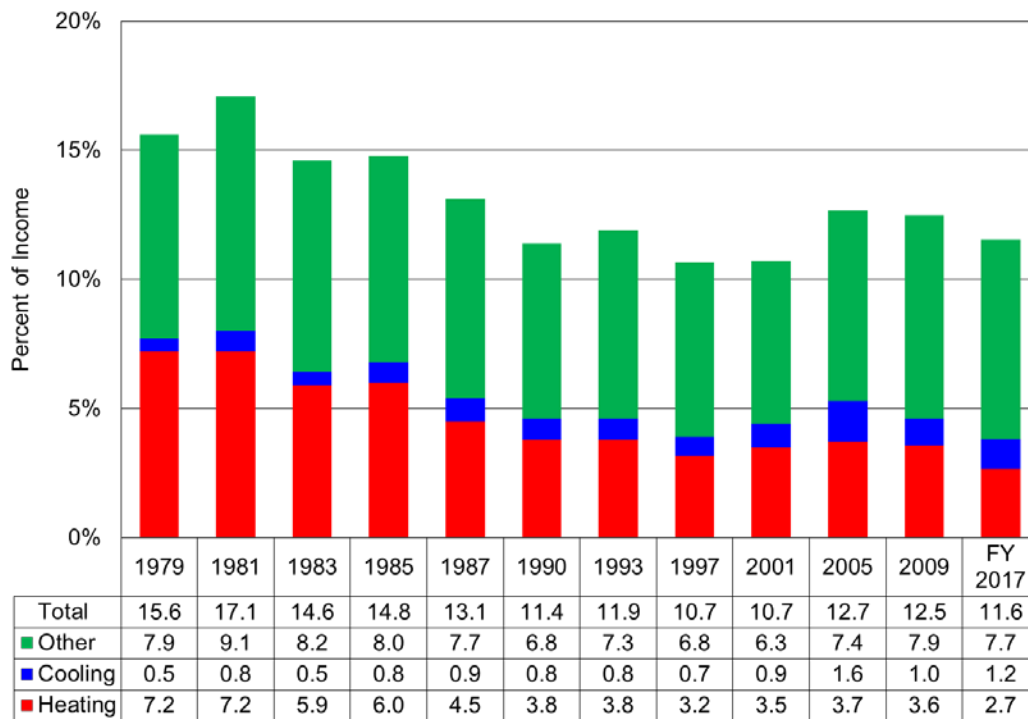

## Low Income Home Energy Trends for FY 2017: II. Low Income Home Energy Trends

- **Median Individual Burden:** Computed by finding, using the RECS data, the energy burden for each individual household in a given set (such as low income households) and finding the median, or middle point, of the distribution of these household-level energy burdens in the set.

Mean group burden is the burden statistic that has been used in the series of *LIHEAP Annual Reports to Congress*. Recent technical research has furnished additional insights on the range of alternative burden summary statistics.<sup>12</sup>

Figure 2-5 shows the time series for mean group energy burdens by end use for low income households. Mean group home energy burden, the sum of the heating and cooling burden components of mean residential energy burden from Figure 2-5, grew from 7.7 percent of income in 1979 to 8.0 percent in 1981, and then fell considerably after 1981 to 3.9 percent in 1997. From 1981 through 1997 mean group home energy burden declined because mean home energy expenditures for low income households fell, while mean incomes for low income households rose. Mean group home energy burden rose to 4.4 percent in 2001, 5.3 percent in 2005, and fell to 4.6 percent in 2009 and 3.9 percent in FY 2017. Mean group home energy burden for FY 2017 was about 26 percent lower than in 2005, about 15 percent lower than in 2009, and about 51 percent below the peak level in 1981.

**Figure 2-5. Mean group residential energy burden by end use for households with incomes at or below 150 percent of HHS Poverty Guidelines, 1979 to FY 2017**

Figures 2-6 and 2-7 show how the mean individual and median individual energy burden statistics compare to the group energy burden statistics. Figure 2-6 shows the trends in residential energy burden for low income households. In 2009, the mean individual residential energy burden was 23.6 percent, significantly higher than the median individual burden of 11.7 percent and the mean group burden of 12.5 percent. For FY 2017, median individual residential energy burden was 10.4 percent – about 31 percent lower than the peak in 1981; mean group residential energy burden was 11.6 percent – about 32 percent lower than the

<sup>12</sup> See Appendix A for additional information on the interpretation of alternative burden statistics.

## Low Income Home Energy Trends for FY 2017: II. Low Income Home Energy Trends

1981 peak; and the mean individual residential energy burden of 21.8 percent was about 8 percent lower than the peak in 2009.

**Figure 2-6. Comparison of mean group, mean individual, and median individual residential energy burden for households with incomes at or below 150 percent of HHS Poverty Guidelines, 1979 to FY 2017**

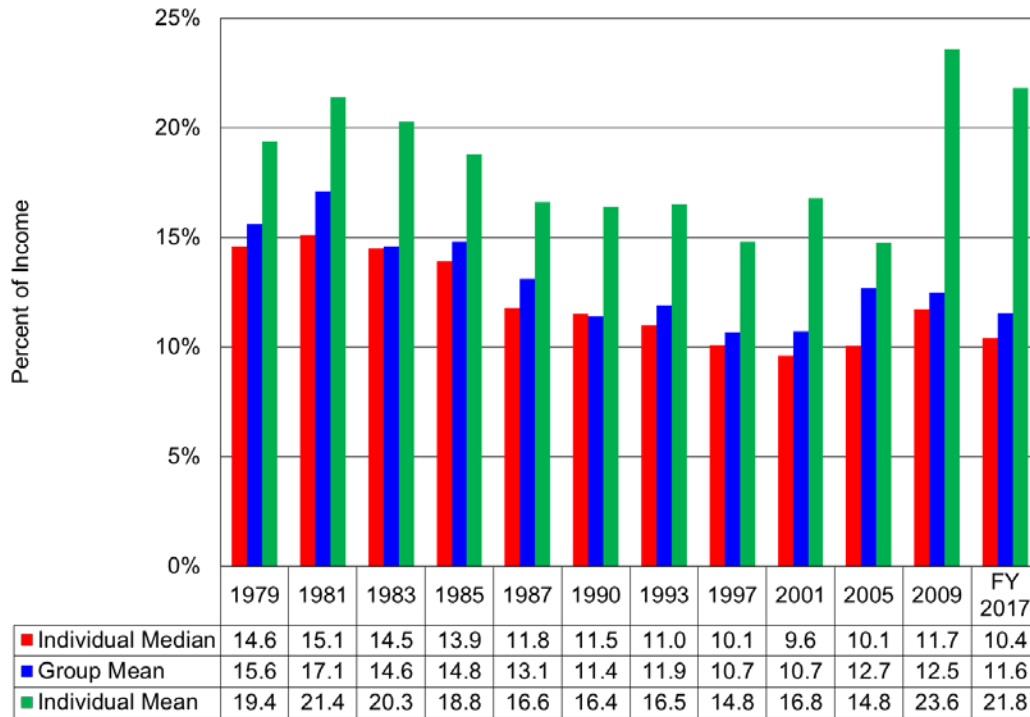

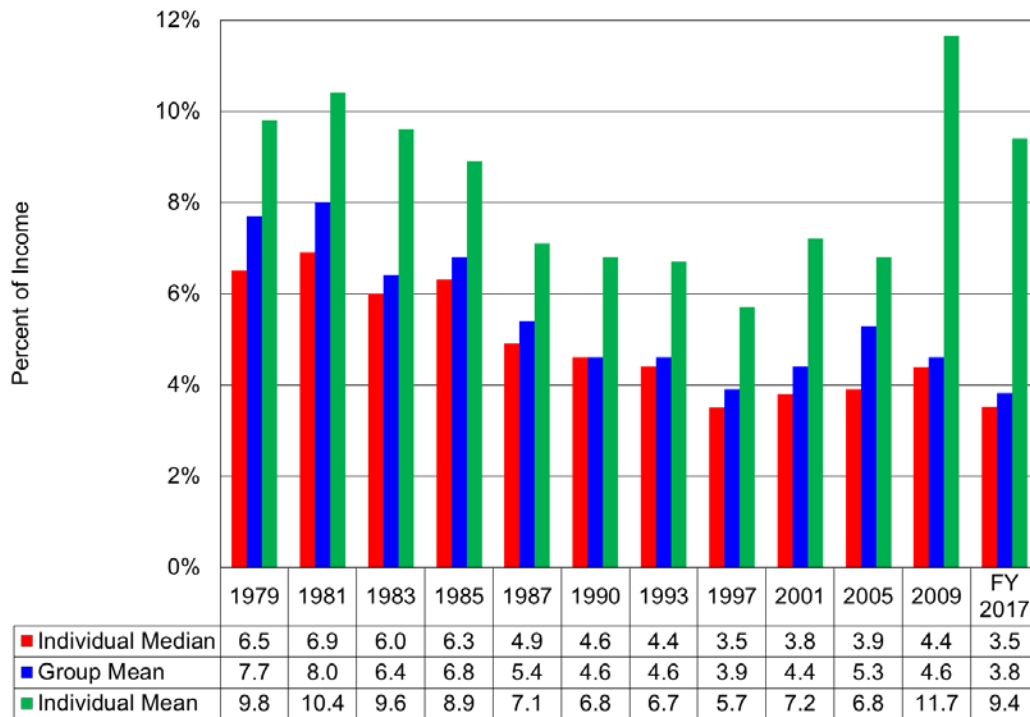

Figure 2-7 shows the trends in home energy burden for low income households. In 2009, the mean individual home energy burden was 11.7 percent, the median individual home energy burden was 4.4 percent, and the mean group home energy burden was 4.6 percent. In FY 2017, the mean individual home energy burden was 9.4 percent, the median individual home energy burden was 3.5 percent, and the mean group home energy burden was 3.8 percent. The lowest home energy burden for the individual median occurred in 1997 and 2017, the lowest home energy burden for the group mean occurred in 2017, and the lowest home energy burden for the individual mean occurred in 1997. The highest home energy burden for the individual median and group mean occurred in 1981, while the highest individual mean occurred in 2009.

**Figure 2-7. Comparison of mean group, mean individual, and median individual home energy burden for households with incomes at or below 150 percent of HHS Poverty Guidelines, 1979 to FY 2017**

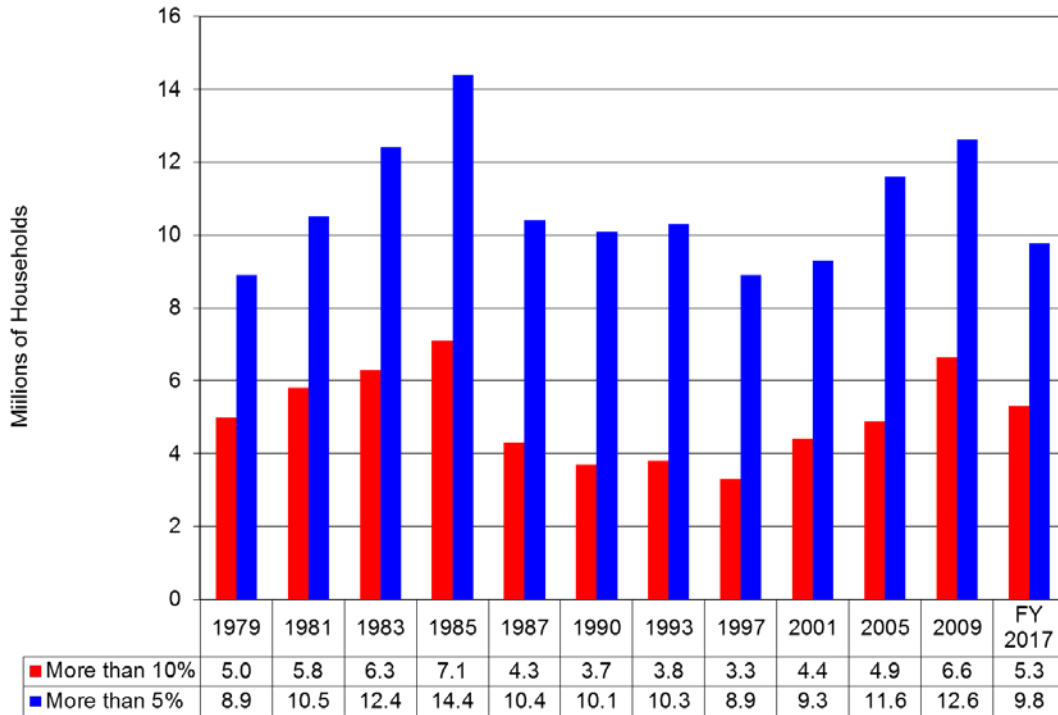

Figures 2-8 and 2-9, on the next page, present information on the number and percent of low income households that had home energy burdens that exceeded specified levels. The levels are reference points and do not represent any judgment regarding an “affordable” level of energy burden.

As shown in Figure 2-8, the number of low income households with home energy burdens exceeding 10 percent of income grew from 5.0 million in 1979 to 7.1 million in 1985, an increase of 42 percent. The number of low income households with home energy burdens exceeding 5 percent of income grew by 62 percent from 1979 to 1985. These increases were primarily the result of growth in the total number of low income households. As Figure 2-9 shows, the percentage of low income households with home energy burdens exceeding 5 percent remained quite stable from 1979 through 1985. However, the percentage of low income households with home energy burdens exceeding 10 percent dropped by 17 percent over that same period.

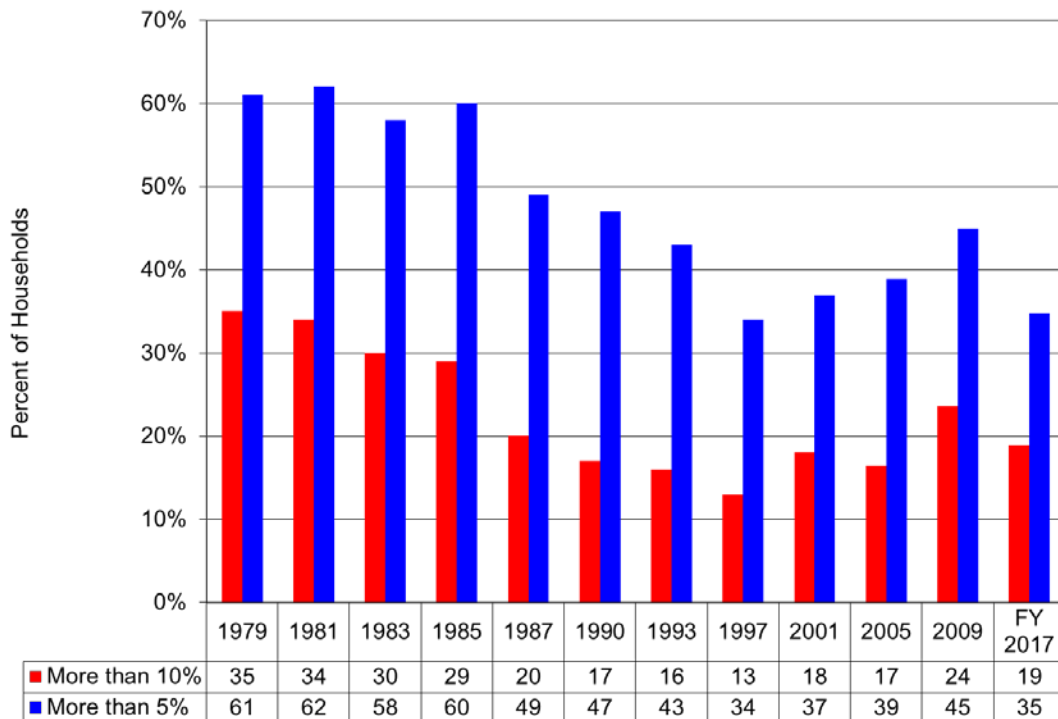

For the period 1985 through 1997, however, both the number and percentage of low income households exceeding specified levels fell significantly from previous levels. For these years, both a reduction in home energy expenditures and increased incomes caused burden to decrease for low income households. In 2001, both the number and percent of households exceeding the specified levels rose. From 2001 to 2009, both the percent of households exceeding the specified levels, and the number of households exceeding the specified levels, increased. In FY 2017, the number of households spending over 10 percent of income on home energy decreased from 6.6 million in 2009 to 5.3 million in FY 2017, and the percent of households decreased by 5 percentage points, from 24 percent in 2009 to 19 percent in FY 2017. Over the same period, the number of households spending over 5 percent of income on home energy decreased from 12.6 million in 2009 to 9.8 million, and the percent of households decreased from 45 percent in 2009 to 35 percent. The number of low income households with home energy burdens exceeding 10 percent of income in FY 2017 was about 25 percent less than the 1985 level yet about 6 percent more than the 1979 level.

## Low Income Home Energy Trends for FY 2017: II. Low Income Home Energy Trends

**Figure 2-8. Number of low income households (in millions) spending over 5 percent and 10 percent of income on home energy, 1979 to FY 2017**

**Figure 2-9. Percent of low income households spending over 5 percent and 10 percent of income on home energy, 1979 to FY 2017**

## Low Income Home Energy Trends for FY 2017: II. Low Income Home Energy Trends

Figure 2-10 shows the total assistance funding that would be required to reduce the home energy burden for all low income households to 10 percent of income and 5 percent of income.<sup>13</sup> The amount required for a reduction in the home energy burden of low income households to 5 percent of income was \$2.2 billion in 1979, \$4.6 billion by 1985, \$3.3 billion in 2001, \$5.5 billion in 2005, \$5.7 billion in 2009, and \$4.1 billion in FY 2017. The number of households with home energy burdens exceeding 5 percent of income fell between 1985 and 1997. The total dollars of assistance funding required to reduce the home energy burden of low income households to 5 percent also fell through 1997. From 1997 to 2005, increased expenditures caused the number of low income households exceeding the percent of income reference points to rise. Accordingly, the total dollars of assistance funding required to reduce the home energy burden to 5 percent also rose substantially. In FY 2017, the number of low income households exceeding the percent of income reference points was less than in 2009. Total dollars of assistance funding required to reduce home energy burden to 10 percent decreased compared to the amount required in 2009 – from \$3.1 billion required in 2009 to \$2.2 billion required in FY 2017. Similarly, the total dollars of assistance funding required to reduce home energy burden to 5 percent decreased compared to the amount required in 2009 – from \$5.7 billion required in 2009 to \$4.1 billion required in FY 2017.

**Figure 2-10. Total fuel assistance dollars (in billions) needed to reduce low income household spending on home energy to 5 percent and 10 percent of income, 1979 to FY 2017**

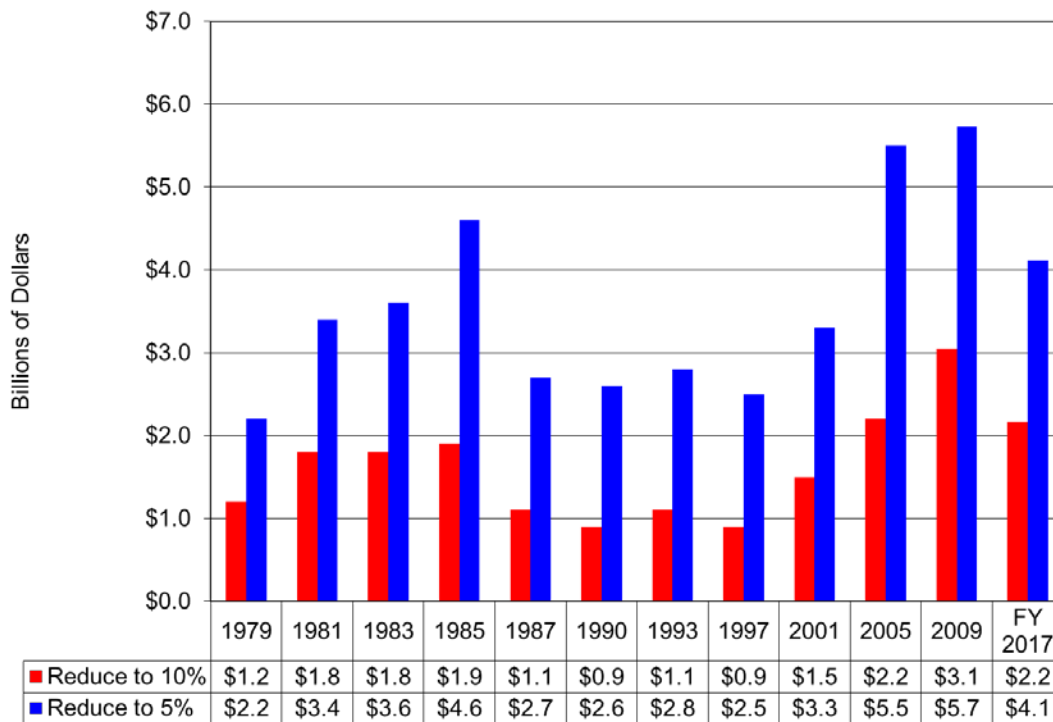

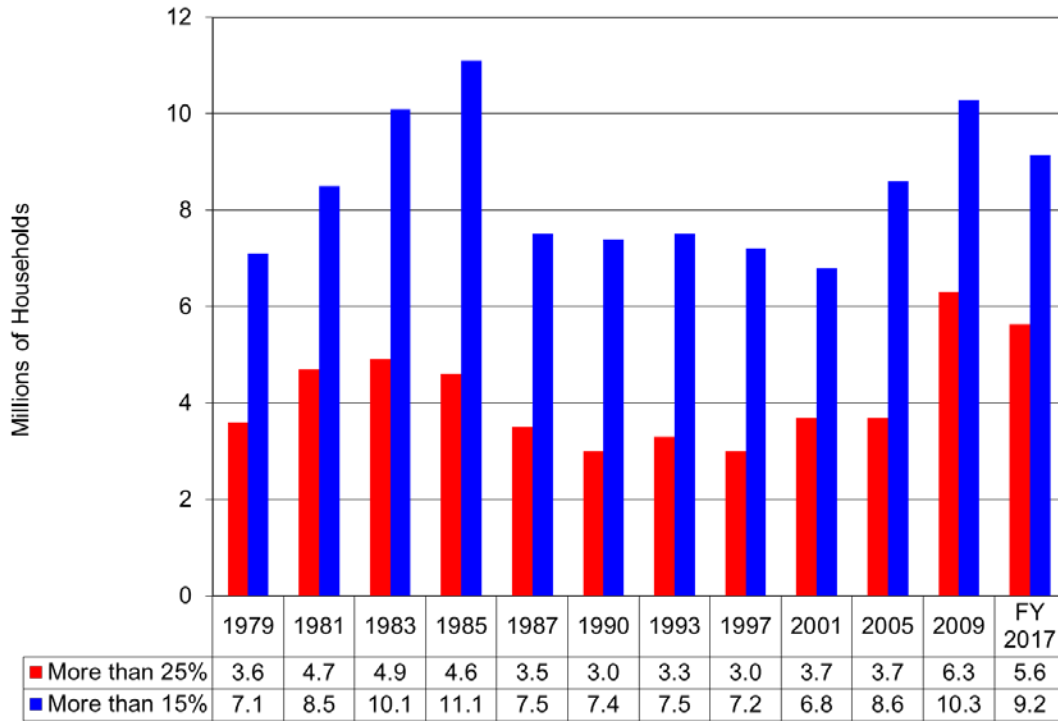

Figure 2-11 on the next page furnishes statistics on the number of low income households that had residential energy expenditures that exceeded specified levels. Figure 2-12 furnishes statistics on total fuel assistance dollars needed to reduce residential energy burden to specified levels. Figure 2-11 shows that the number of households spending over 15 and 25 percent of their income on residential energy followed a pattern similar to that observed in Figure 2-8. The largest number of low income households exceeding 15 percent of income spent on residential energy occurred in 1985, followed by 2009 and 1983,

<sup>13</sup> This is calculated first by finding the amount of funds for each low income household that would be required to reduce its home energy burden to the specified percent of income. This amount is the difference between the household's actual home energy burden and the specified home energy burden (the dollar amount of the specified percent of household income). Then the household amounts are aggregated to produce the total assistance funding that is needed for all low income households.

## Low Income Home Energy Trends for FY 2017: II. Low Income Home Energy Trends

respectively. The largest number of low income households exceeding 25 percent of income spent on residential energy occurred in 2009, followed by FY 2017. Figure 2-12 demonstrates that the funding assistance required to reduce spending on residential energy by all low income households to the specified percentages reached its highest level in 2009, followed by FY 2017.

**Figure 2-11. Number of low income households (in millions) spending over 15 percent and 25 percent of income on residential energy, 1979 to FY 2017**

**Figure 2-12. Total fuel assistance dollars (in billions) needed to reduce low income household spending on residential energy to 15 percent and 25 percent of income, 1979 to FY 2017**

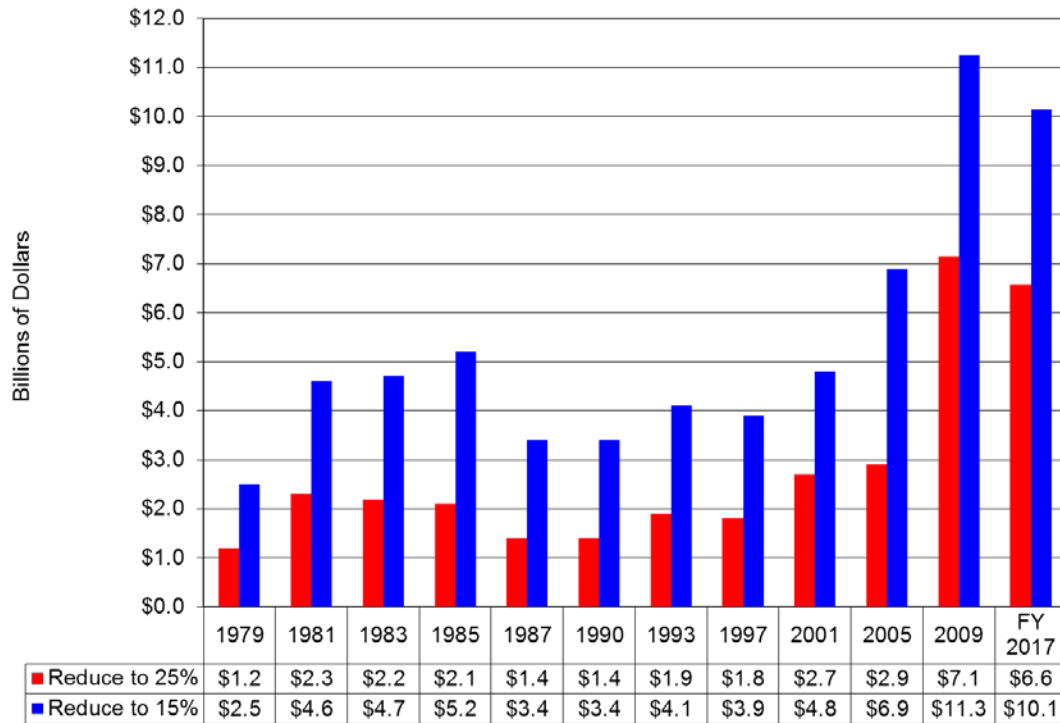

Figure 2-13 shows how the aggregated residential energy bill for all low income households has changed from 1979 to FY 2017. In 1979, the aggregated home energy bill (heating costs plus cooling costs) for low income households was \$4.5 billion. By FY 2017, the aggregated home energy bill had grown to about \$14.5 billion. This growth results from both the increase in average home energy bills and growth in the size of the low income population.

Figure 2-13 also shows that in 1979, home energy costs accounted for about half of the total low income residential energy bill. In FY 2017, home energy costs accounted for about 33 percent of the total low income residential energy bill.

## Low Income Home Energy Trends for FY 2017: II. Low Income Home Energy Trends

**Figure 2-13. Aggregated residential energy expenditures (in billions of dollars) by end use for households with incomes at or below 150 percent of HHS Poverty Guidelines, 1979 to FY 2017**

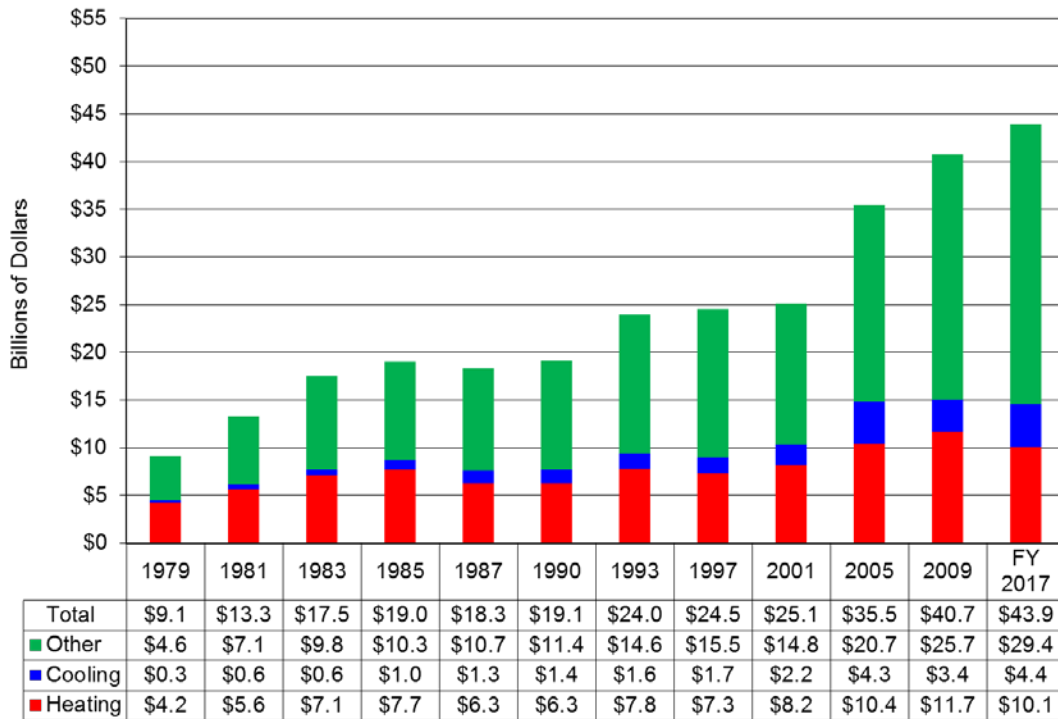

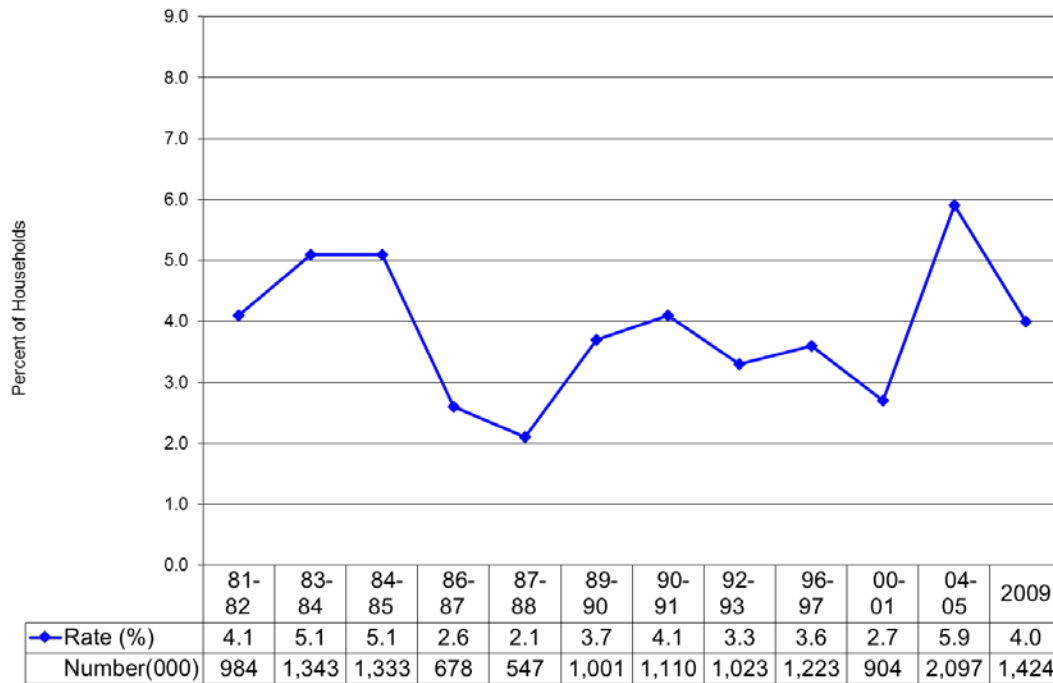

Figure 2-14, on the next page, demonstrates the impact of the inability to afford home energy on LIHEAP income eligible households. It shows the number of LIHEAP income eligible households that reported that they were unable to use their main source of heat for a period of two hours or more during the heating season because they were unable to pay for their main heating fuel. In 1981-82, 984 thousand LIHEAP income eligible households (4.1 percent of LIHEAP income eligible households) had heat interruptions during the heating season. The number and percentage grew to 1.34 million (5.1 percent) in 1983-84 and then fell consistently to 547 thousand (2.1 percent) in 1987-1988. In 1989-90 there was a sharp increase to 1.0 million (3.7 percent). This higher level of heat interruptions was sustained in 1990-91 when 1.1 million (4.1 percent) LIHEAP income eligible households had heat interruptions and in 1992-93 when 1.0 million (3.3 percent) LIHEAP income eligible households had heat interruptions. The number and percentage increased to 1.2 million (3.6 percent) in 1996-97. In 2000-01, the number and percentage of LIHEAP income eligible households with heat interruptions decreased to 904 thousand (2.7 percent). The number and percentage increased substantially to 2.1 million (5.9 percent) in 2004-2005. In 2009, 1.4 million (4.0 percent) LIHEAP income eligible households had heat interruptions due to bill-payment related problems for the household's main heating fuel.<sup>14</sup>

<sup>14</sup> Data for 2009 exclude those households heating with other fuels that were unable to use their heating equipment because the electric company disconnected service for nonpayment and electricity was needed to run the heating equipment.

**Figure 2-14. Percentage of LIHEAP income eligible households with heat interruptions of two hours or more caused by an inability to pay for energy to run the household's main heating system, 1981-82 heating season to calendar year 2009<sup>1</sup>**

<sup>1</sup> The 2009 RECS collected information on heating interruptions for calendar year 2009, not for the heating season. Data for 2004-2005 heating season and 2009 refer to heat interruptions of any length. Data for the 1981-82 heating season refer to heat interruptions of one day or more. Data for 2009 exclude those households heating with other fuels that were unable to use their heating equipment because the electric company disconnected service for nonpayment and electricity was needed to run the heating equipment. Between 10 and 15 percent of heat interruptions for LIHEAP income eligible households last at least 2 hours but less than 24 hours. The procedures for analyzing heat interruption data have changed since the issuance of the *LIHEAP Report to Congress for FY 1993*. The heat interruption rates for 1983-84 through 1987-88 are slightly higher with this new analysis.

## Analysis of energy price and energy efficiency trends

A number of factors underlie the energy consumption and expenditures trends. Three of the most important factors are fuel prices, weather, and energy efficiency. Figures 2-15, 2-16, and 2-17 furnish information on trends in these factors.

Figure 2-15, on the next page, furnishes an index of average fuel prices compared to an index of inflation that is based upon the Consumer Price Index (CPI). The fuel price index shows the percentage change from 1979 to FY 2017. For example, the CPI-based inflation index grew from 100 in 1979 to 125 in 1981, indicating a 25 percent increase in consumer prices. Figure 2-15 shows that fuel prices outpaced the overall level of inflation from 1979 through 1983. The CPI increased by 37 percent during that period, while the composite average of fuel prices increased by 81 percent. From 1983 through 1997, the increase in the composite average of fuel prices moderated somewhat and generally grew more slowly than the CPI. However, from 1997 to 2005, the pattern was reversed; the composite average fuel price index grew by over 45 percent while the CPI grew by only 22 percent. The rapid growth of prices from 1979 through 1983 explains why residential energy expenditures per low income household rose so rapidly (Figure 2-4) while consumption was declining (Figure 2-3). The moderate growth in fuel prices from 1985 to 1997 (19 percent) explains why residential energy expenditures per low income household rose slightly during that

## Low Income Home Energy Trends for FY 2017: II. Low Income Home Energy Trends

period. In 2009, fuel prices increased by about 15 percent over 2005 prices. The increase in fuel prices explains why expenditures also rose. In FY 2017, fuel prices increased by about 8 percent over 2009 prices and once more contributed to an increase in expenditures. For low income households, residential energy expenditures also increased from 2009 to FY 2017 (see Figure 2-4).

**Figure 2-15. Index of dollar prices for fuel oil, natural gas, electricity, and a composite compared to the Consumer Price Index (CPI), 1979 to FY 2017**

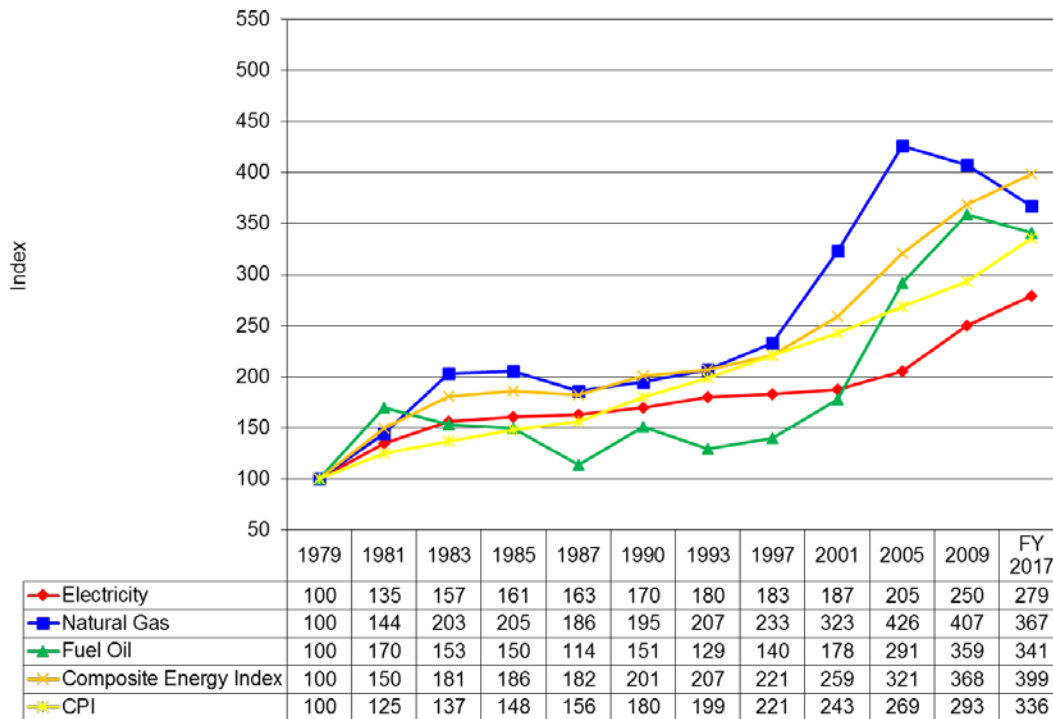

Figure 2-16 shows the changes in heating energy consumption among low income households from 1979 to FY 2017 compared to changes in heating degree days for the same period. From 1979 to 1983, home heating consumption fell more rapidly than did heating degree days, suggesting a significant increase in efficiency as a result of conservation measures or actions. Consumption per heating degree day dropped rapidly for that period. From 1983 to 1997, there was only a moderate reduction in consumption per heating degree day. Thus, heating consumption fluctuations appear to be primarily a result of the changes in the weather for those years. From 1997 to 2005, home heating consumption again fell more rapidly than did heating degree days, suggesting a moderate increase in efficiency as a result of conservation measures or actions. This was perhaps driven by the high fuel prices experienced in 2001 and 2005. From 2005 to 2009, there was a slight reduction in consumption per heating degree day. The consumption per heating degree day was about the same in FY 2017 as in 2009.

## Low Income Home Energy Trends for FY 2017: II. Low Income Home Energy Trends

**Figure 2-16. Index of heating consumption, heating degree days, and heating consumption per heating degree day for households with incomes at or below 150 percent of HHS Poverty Guidelines, 1979 to FY 2017**

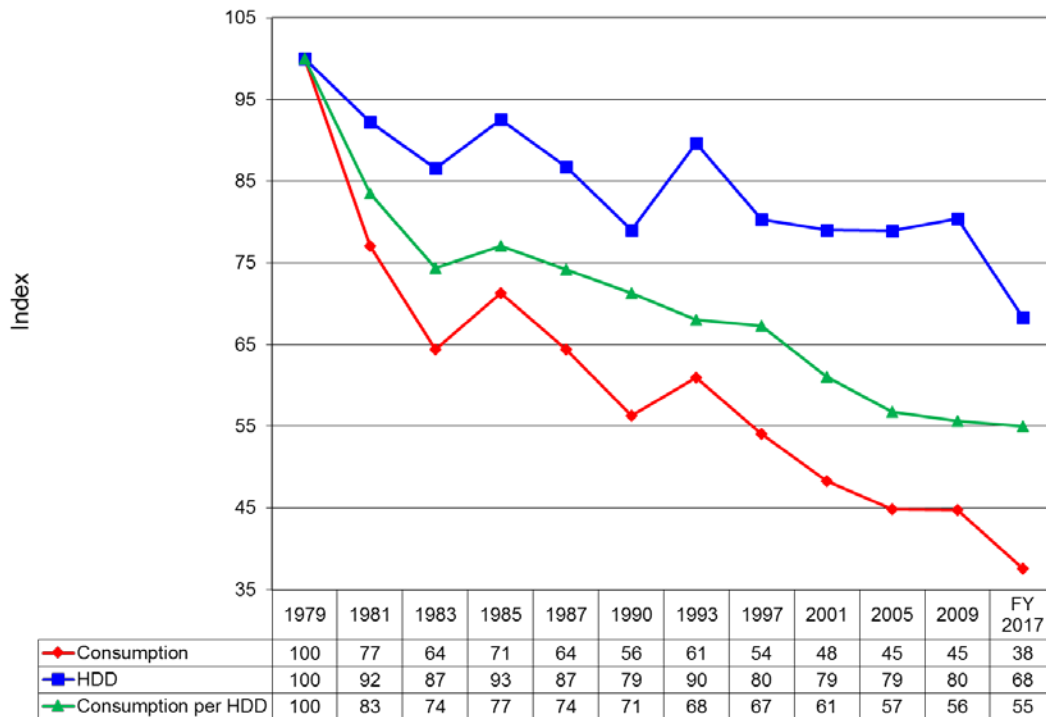

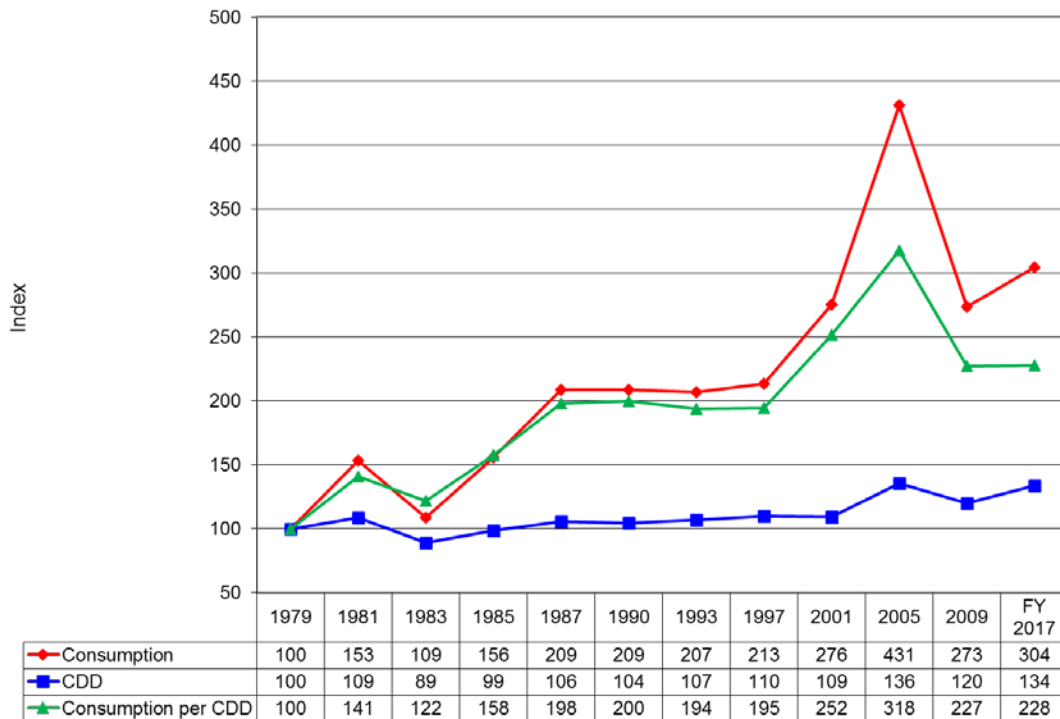

Figure 2-17 shows that home cooling consumption trends among low income households are somewhat more complex than are home heating consumption trends. In FY 2017, mean home cooling consumption was much higher than it was in 1979, even though households experienced a relatively smaller increase in cooling degree days. Thus, mean consumption per cooling degree day increased substantially from 1979 to FY 2017, making it appear as though there was a reduction in efficiency. However, the primary cause of the increase in mean home cooling consumption was the large increase in the availability of air-conditioning among low income households.<sup>15</sup> As shown in Figure 2-2, only 37 percent of low income households had air-conditioning in 1979, while in 2009, about 77 percent of low income households had air-conditioning. Because of this fundamental change in the number of households that use air-conditioning, it is very difficult to assess either changes in efficiency from 1979 to FY 2017 or year-to-year changes in consumption in response to changes in cooling degree days.

<sup>15</sup> Air-conditioning equipment includes central air conditioners and window or wall units, ceiling fans, and evaporative coolers. The availability of all household appliances increased for low income households over this period due to the overall increase in the wealth of the nation and the decrease in the cost of older technologies.

## Low Income Home Energy Trends for FY 2017: II. Low Income Home Energy Trends

**Figure 2-17. Index of cooling consumption, cooling degree days, and cooling consumption per cooling degree day for households with incomes at or below 150 percent of HHS Poverty Guidelines, 1979 to FY 2017**

Figures 2-18 and 2-19, on the next page, show that the mean group energy burden for low income households is substantially higher than that for all households. In FY 2017, the mean group home energy burden for all households was 0.9 percent and 3.8 percent for low income households. In FY 2017, the mean group residential burden was 2.5 percent for all households and 11.6 percent for low income households. Over time, the gap between the burden for low income households and all households has fluctuated somewhat. Figure 2-18 shows that in 1979, the mean group home energy burden for low income households was just over 4 times that of all households, while in 1993, the mean group burden for low income households was close to 3.5 times that of all households. However, in FY 2017, the mean group burden for low income households was again over 4 times that of all households.

## Low Income Home Energy Trends for FY 2017: II. Low Income Home Energy Trends

Figure 2-18. Mean group home energy burden for all households and for households with incomes at or below 150 percent of HHS Poverty Guidelines, 1979 to FY 2017

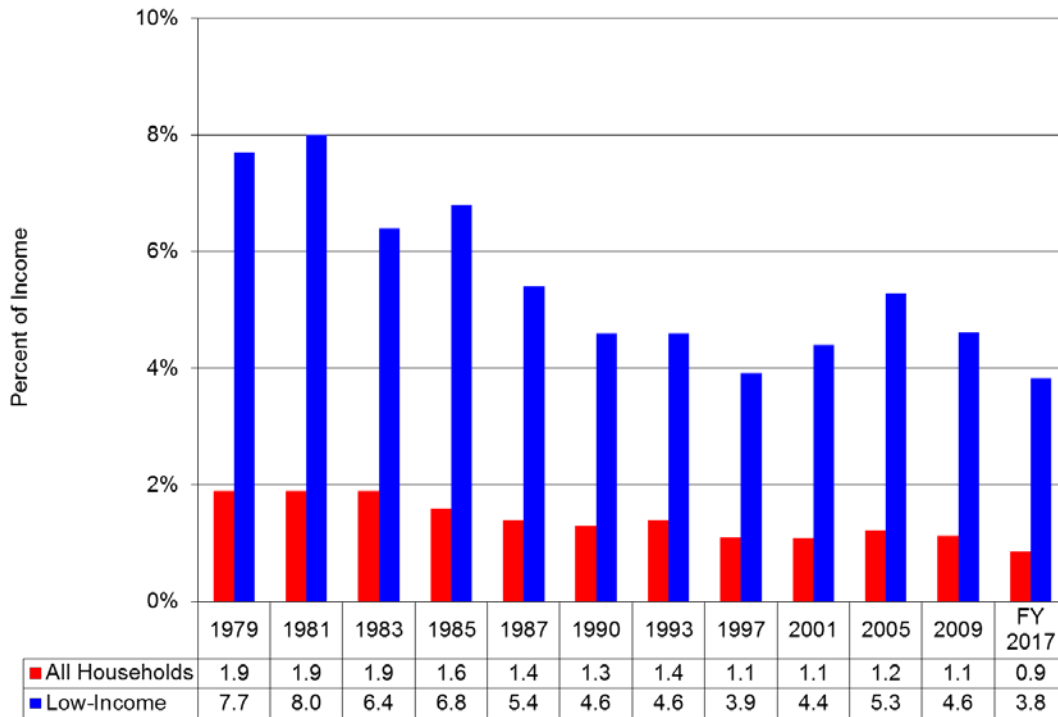

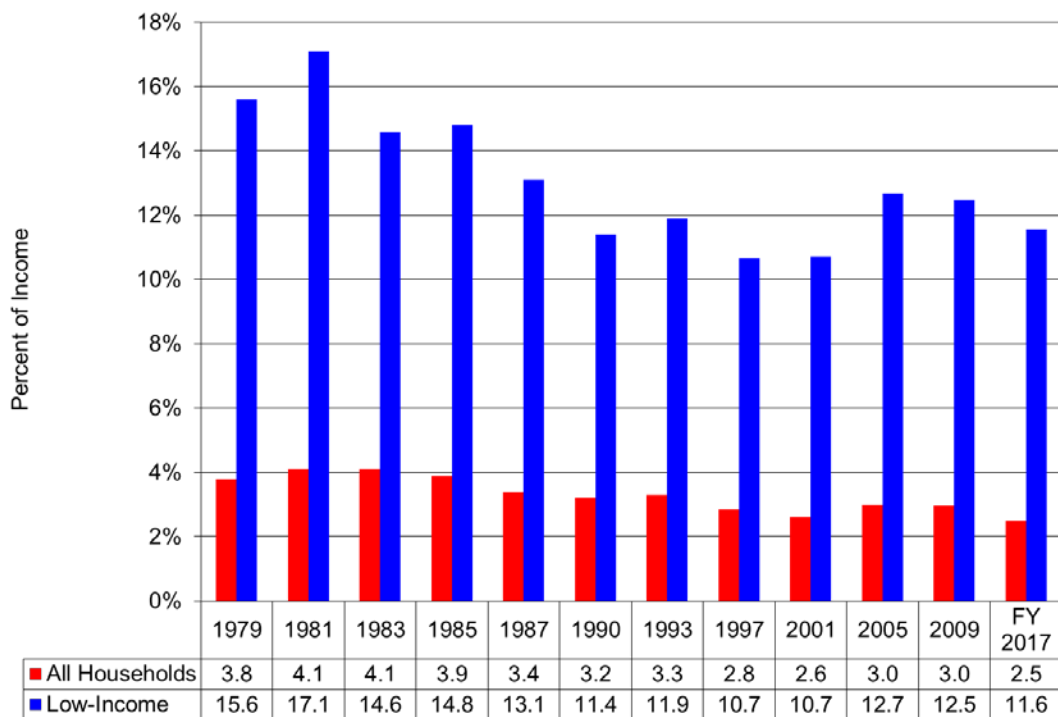

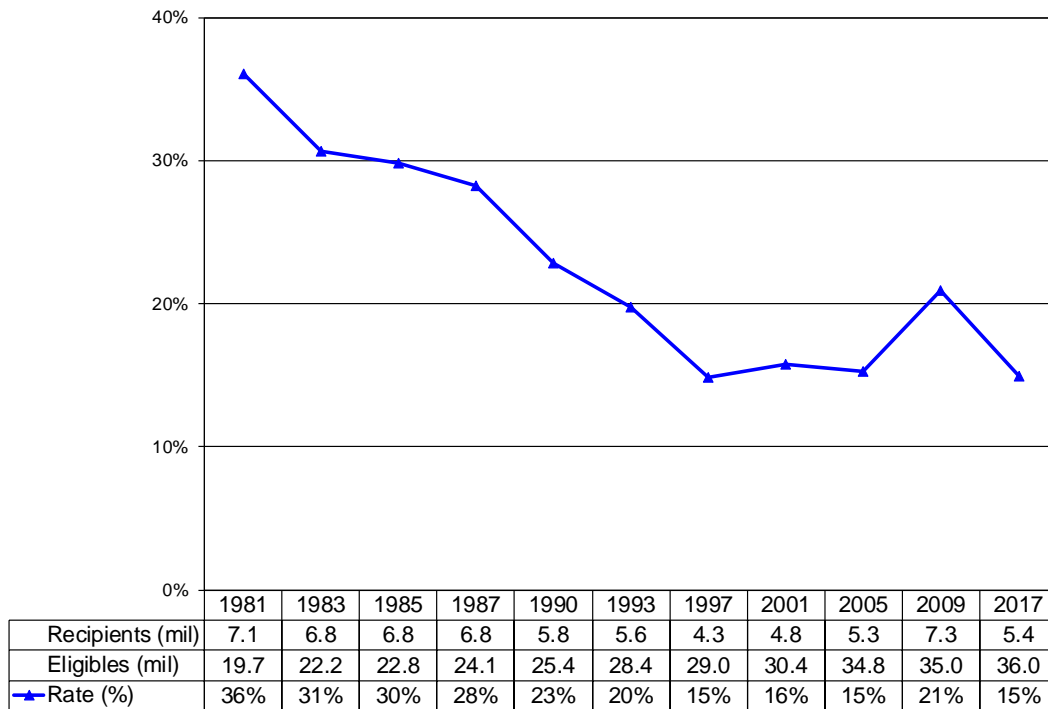

Figure 2-19. Mean group residential energy burden for all households and for households with incomes at or below 150 percent of HHS Poverty Guidelines, 1979 to FY 2017

## Trends in LIHEAP

Figures 2-20 through 2-24 furnish information on trends for HHS's energy assistance programs from FY 1981 through FY 2017.<sup>16</sup> Figure 2-20 shows that the percentage of LIHEAP income eligible households that have received heating and/or winter crisis assistance had fallen steadily until 1997 but remained steady at about 15 percent since then, with an exception in FY 2009 when the percentage increased to about 21 percent.<sup>17</sup> In FY 1981, 36 percent of eligible households received heating and/or winter crisis assistance benefits; this number fell to 15 percent in 1997. In FY 2017, 15 percent of LIHEAP income eligible households received those benefits. Figure 2-21, on the next page, furnishes statistics on the count of recipients by benefit type.

**Figure 2-20. Percentage of LIEAP/LIHEAP federally income eligible households receiving LIEAP/LIHEAP heating and/or winter crisis assistance, FY 1981 to FY 2017**

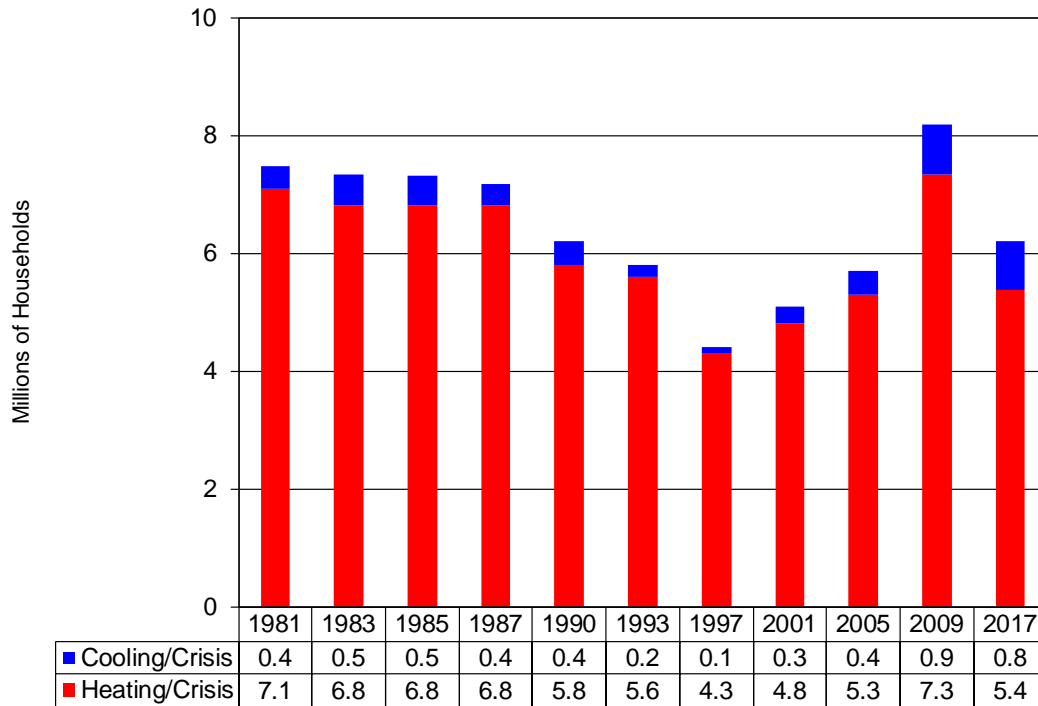

SOURCE: HHS Administrative Data — such data for FY 2017 are preliminary; thus the actual figures may differ.

NOTE: The FY 1981 estimate of income eligible households is not directly comparable to those of the other years because the income eligibility guidelines for the FY 1981 program differed from those of other years.

<sup>16</sup> Note that the federal income eligibility guidelines for the FY 1981 Low Income Energy Assistance Program (LIEAP) were different from the LIHEAP programs in other years included in the table. The federal income eligibility guidelines for the FY 1981 LIEAP program were based on the Lower Living Standard of the Bureau of Labor Statistics, whereas the federal income eligibility guidelines for the other years included in the table are based on the HHS Poverty Guidelines and state median income estimates.

<sup>17</sup> The number of recipient households increased in FY 2009 as a result of greater funding appropriated to LIHEAP. In addition, in FY 2009, the federal income eligibility guidelines were increased to the greater of 150 percent of HHS Poverty Guidelines or 75 percent of the state median income estimates. However, analysis of actual income guidelines implemented by the states in FY 2009 shows that few states increased their eligibility guidelines as a result, and most households served by state LIHEAP programs in FY 2009 had incomes at or below the traditional federal income eligibility guidelines (greater of 150 percent of HHS Poverty Guidelines or 60 percent of the state median income estimates). As a result, the number of federally income eligible households for FY 2009 listed in the table and the "Trends in LIHEAP" section are based on the greater of 150 percent of HHS Poverty Guidelines or 60 percent of the state median income estimates to 1) maintain consistency with prior and future years, and 2) provide estimates based on the "effective" guidelines in place during FY 2009.

**Figure 2-21. Number of households receiving LIEAP/LIHEAP heating and/or winter crisis assistance or cooling and/or summer crisis assistance, FY 1981 to FY 2017**

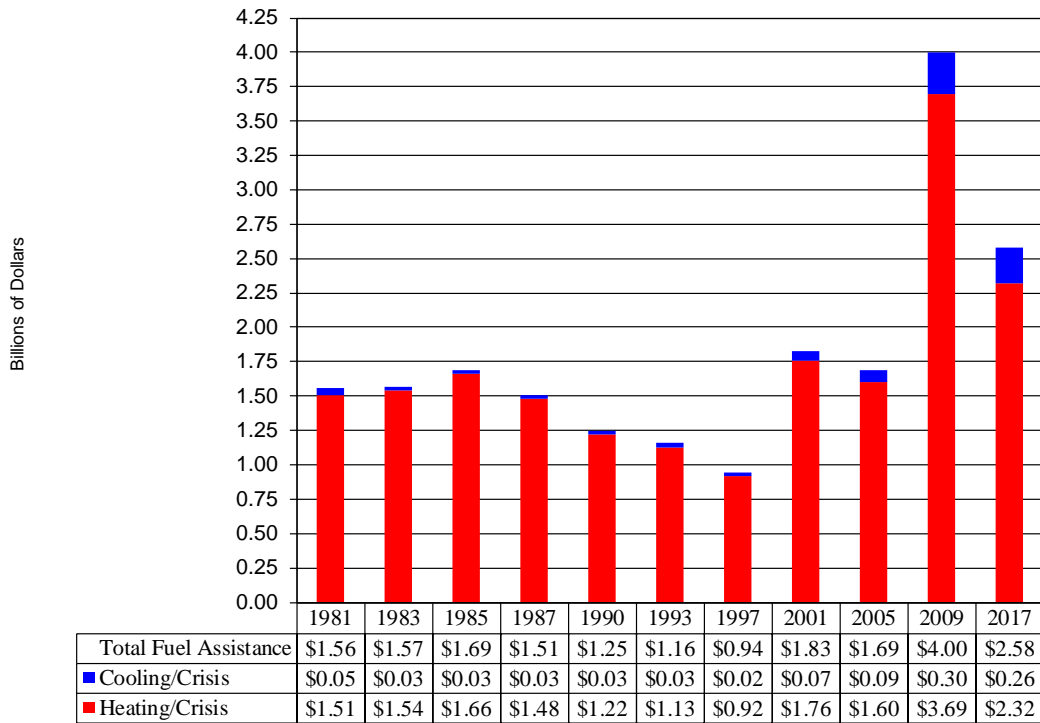

NOTE: Cooling assistance/summer crisis figures cannot be added to heating assistance/winter crisis figures to generate total assistance + crisis figures for each year because households can receive more than one type of assistance.

SOURCE: HHS Administrative Data — such data for FY 2017 are preliminary; thus the actual figures may differ.

Figure 2-22, on the following page, shows that the total funds used for fuel assistance benefits have fluctuated over time. For the years shown, funding was highest in FY 2009, when \$4.0 billion were used for heating and cooling assistance benefits, and lowest in FY 1997, when \$0.94 billion were used for assistance benefits. About \$2.58 billion were used for heating and cooling assistance benefits in FY 2017.

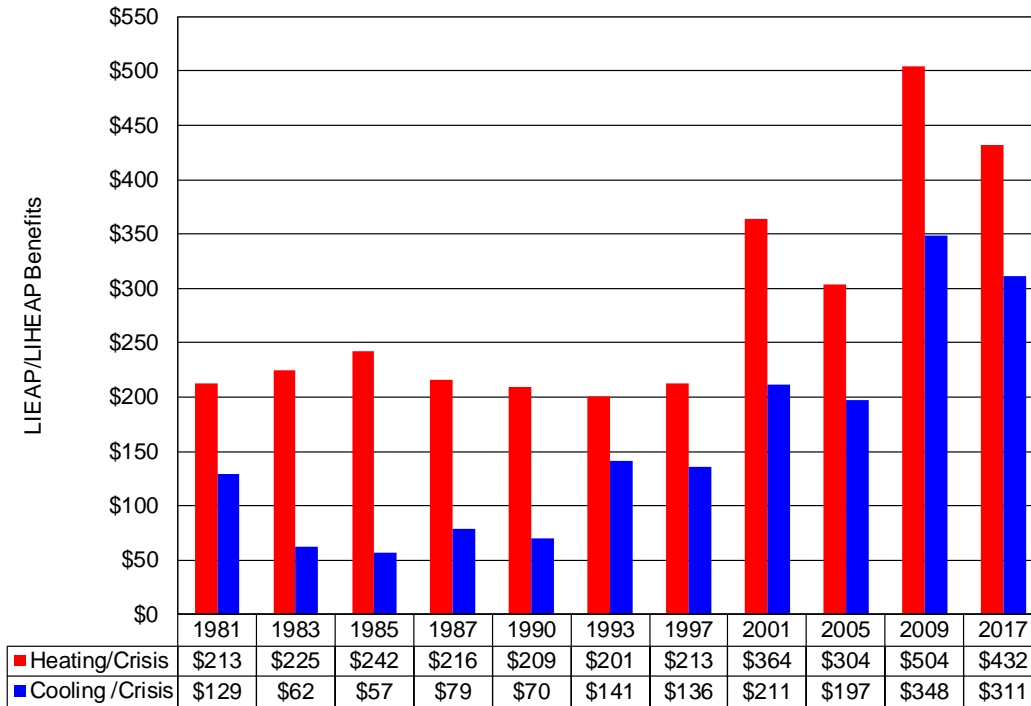

**Figure 2-22. Funds used for LIEAP/LIHEAP fuel assistance, FY 1981 to FY 2017**

SOURCE: HHS Administrative Data — such data for FY 2017 are preliminary; thus the actual figures may differ.

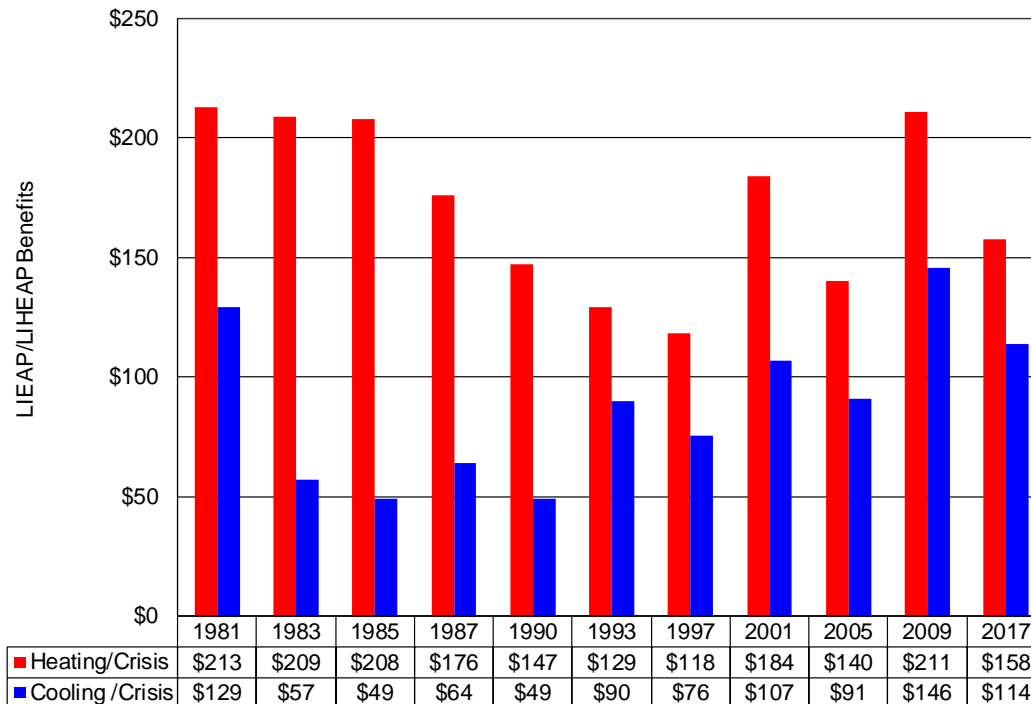

Figure 2-23 on the following page shows that, for the years shown, mean heating/winter crisis benefits were \$213 in FY 1981, grew to \$242 in FY 1985, fell back to \$213 in 1997, rose to \$364 in FY 2001, dropped to \$304 in FY 2005, and then rose substantially to a peak of \$504 in FY 2009. In FY 2017, mean heating/winter crisis benefits dropped to \$432. Figure 2-24 shows that, after adjusting for inflation, the mean value of benefits has fallen substantially, with a fluctuating resurgence beginning in FY 2001. The mean value of heating and/or winter crisis benefits, in 1981 dollars, fell from \$213 in FY 1981 to \$140 in FY 2005. In FY 2009, the mean value of heating benefits, in 1981 dollars, increased considerably to \$211 but decreased to \$158 in FY 2017. With the exception of FY 1981, mean cooling benefits, in 1981 dollars, ranged from \$49 to \$90 through FY 1997, then rose to \$107 in FY 2001 before falling to \$91 in FY 2005. In FY 2009, mean cooling benefits, in 1981 dollars, increased substantially to \$146, only to fall again to \$114 in FY 2017. In FY 1993, one state made program changes that significantly increased the mean benefit and decreased the total number of recipients.

**Figure 2-23. Mean combined LIEAP/LIHEAP heating and/or winter crisis benefits and mean cooling and/or summer crisis benefits, in nominal dollars, FY 1981 to FY 2017**

**Figure 2-24. Mean combined LIEAP/LIHEAP heating and/or winter crisis benefits and mean cooling and/or summer crisis benefits, in real 1981 dollars, FY 1981 to FY 2017**

SOURCE: HHS Administrative Data — such data for FY 2017 are preliminary; thus the actual figures may differ.

## **Analysis of LIHEAP benefits**

The impact of LIHEAP heating benefits can be examined in at least two ways. Figure 2-25, on the next page, shows the share of the aggregated total of low income home heating costs covered by LIHEAP heating and winter crisis benefits (LIHEAP heating coverage). Figure 2-26, on the following page, shows the reduction in mean group home heating burden as a result of LIHEAP benefits (LIHEAP burden offset).

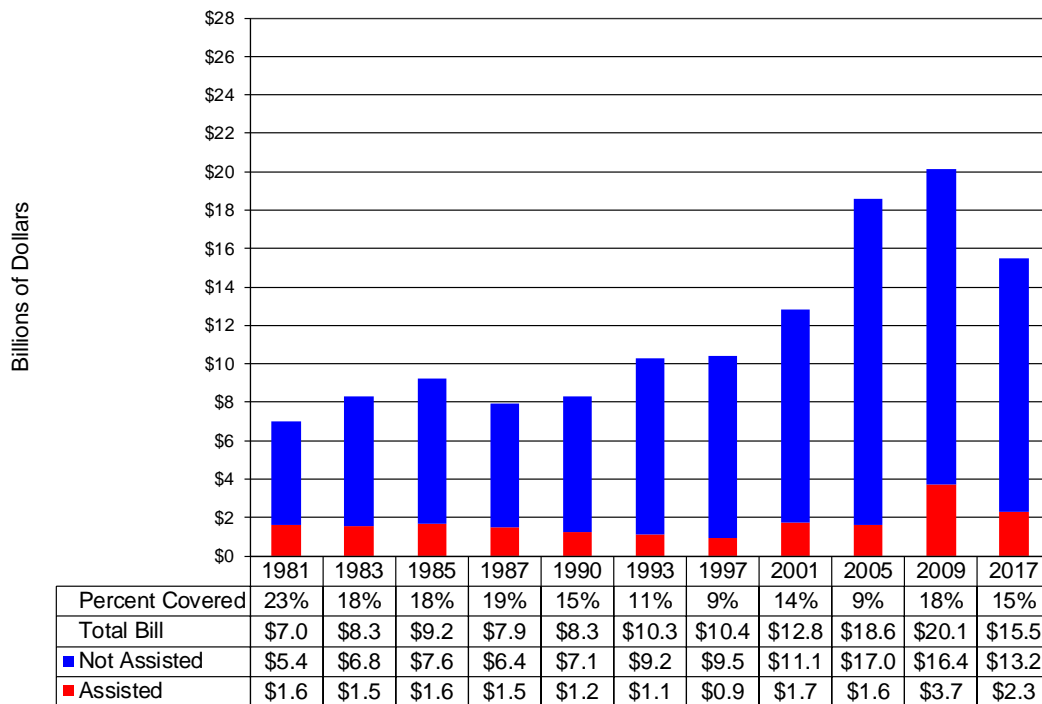

Figure 2-25 shows that the LIHEAP heating coverage rate fell from 23 percent in FY 1981 to 15 percent in FY 2017. The decrease in the LIHEAP heating coverage rate is the result of an increase in the size of the heating bill and an increase in the number of households that were income eligible for assistance benefits in FY 2017.

Figure 2-26 shows that the net effect of LIHEAP has been to lower recipients' group home heating burden to levels that are much closer to the levels of the average household. In FY 1981, the gross mean group home heating burden for LIHEAP recipient households was 8.5 percent, while the net mean group home heating burden (with home heating expenditures taken after deducting LIHEAP benefits) was 2.9 percent. In FY 2017, the gross mean group home heating burden for LIHEAP recipients was 3.4 percent, while the net mean group home heating burden was 0.6 percent. It is interesting to note that, while the gross mean group home heating burden for LIHEAP recipients fell from 8.5 percent in FY 1981 to 4.0 percent in FY 1997, decreases in mean LIHEAP benefits in relation to household income caused the net mean group home heating burden to range between 1.3 and 2.2 times as high as the gross mean group home heating burden for all households except for FY 2005 when that ratio was more than 3 to 1 and FY 2017 when the ratio was 1.4 to 1. In FY 2001, significant increases in the mean heating benefit caused the net mean group home heating burden for LIHEAP recipients to fall to 1.7 percent, however it remained twice as high as the mean group burden for all households. In FY 2005, the mean heating benefit decreased by 16 percent, and net mean group home heating burden almost doubled, increasing by 94 percent. The changes in net mean group heating burden resulted from the combination of a decrease in the mean heating benefit and much higher fuel prices in FY 2005. In FY 2009, the net mean group home heating burden for LIHEAP recipients decreased to 1.4 percent, and in FY 2016 it decreased to 0.8 percent.

## Low Income Home Energy Trends for FY 2017: II. Low Income Home Energy Trends

**Figure 2-25. Amount and percentage of total home heating billed amounts for LIEAP/LIHEAP income eligible households covered by LIEAP/LIHEAP heating and winter crisis benefits, FY 1981 to FY 2017**

Net Burden = (Mean Expenditures - Mean Benefit) / Mean Income

## **Appendix A: Home Energy Estimates**

Appendix A provides information on how estimates of home energy data were derived from the 2009 Residential Energy Consumption Survey (RECS) and updated for FY 2017. The following topics are covered in this Appendix.

- Description of RECS.
- Strengths and limitations of RECS data.
- Energy burden.

### **Description of RECS**

The RECS is a national household sample survey that provides information on residential energy use. It has been conducted by the Energy Information Administration (EIA) of the U.S. Department of Energy (DOE) since 1978. It is designed to provide reliable data at the national and Census regional levels. The RECS includes information on energy consumption and expenditures, household demographics, housing characteristics, weatherization/conservation practices, home appliances, and type of heating and cooling equipment. Currently, this survey is conducted every four years.

The survey consists of three parts:

- EIA interviews households for information about which fuels are used, how fuels are used, energy-using appliances, structural features, energy-efficiency measures taken, demographic characteristics of the household, heating interruptions, and receipt of energy assistance.
- EIA interviews rental agents for households whose rent includes some portion of their energy bill. This information augments information from those households that may not be knowledgeable about the fuels used for space heating or water heating.
- After obtaining permission from respondents, EIA mails questionnaires to their energy suppliers to collect the actual billing data on energy consumption and expenditures. This fuel supplier survey eliminates the inaccuracy of self-reported data. When a household does not consent or when fuel consumption records are unusable or nonexistent, regression analysis is used to impute missing data.<sup>18</sup>

The 2009 RECS is the thirteenth survey in the series of surveys.<sup>19</sup> For the 2009 RECS, 12,083 households were interviewed, including 724 verified LIHEAP recipient households. For the figures in this report, 2009 RECS consumption and expenditure data were updated using price and weather data to represent consumption and expenditures for FY 2017.

---

<sup>18</sup> Regression analysis is a statistical tool for evaluating the relationship of one or more independent variables to a single continuous dependent variable. Formulas developed from regression analysis are used to predict the value of the dependent variable under varying conditions of the independent variable(s).

<sup>19</sup> More information about the RECS sample design, see Energy Information Administration, *Sample Design for the Residential Energy Consumption Survey*, DOE/EIA-0555 (94)/1, Washington, DC, August 1994. The data collected from the 2009 RECS are available from the EIA website: *RECS Survey Data*, Energy Information Administration, <http://www.eia.gov/consumption/residential/data/2009/>

## **Strengths and limitations of RECS data**

The RECS provides the most recent, comprehensive data on home energy consumption and expenditures. The strengths of using RECS to derive home energy estimates are as follows.

- RECS uses a representative national household sample, providing statistically reliable estimates for all, non-low income, and low income households.
- The 2009 RECS included an oversample of LIHEAP recipient households that is representative of the population of LIHEAP heating and cooling assistance recipients.
- The RECS includes usage data for all residential fuels.
- Energy suppliers provide information on actual residential energy consumption and expenditures of RECS sample households in order to eliminate the inaccuracy of self-reported data.
- Regression analyses of RECS data provide estimates of the amounts of fuels going to various end uses, including home heating and cooling.

While the updated 2009 RECS data provide the most current and comprehensive data on residential energy use by low income households, several significant limitations must be addressed:<sup>20</sup>

- The 2009 RECS data for calendar year 2009 were updated to FY 2017 (October 1, 2016 to September 30, 2017), using procedures that adjust the 2009 data to reflect the weather and fuel prices for FY 2017. These procedures are comparable to those used for the FY 1986 - FY 2016 annual LIHEAP Reports to Congress. However, the reader should exercise caution in comparing the data in this report with data in annual LIHEAP Reports to Congress prior to FY 1986, in which consumption and expenditure data were estimated from the RECS year (April 1 to March 31).
- The household is a basic reporting unit for RECS and LIHEAP. RECS defines a household as all individuals living in a housing unit, whether related or not, who (1) share a common direct access entry to the unit from outside the building or from a hallway, and (2) do not normally eat their meals with members of other units in the building. A household does not include temporary visitors or household members away at college or in the military. LIHEAP defines a household as one or more individuals living together as an economic unit who purchase energy in common or make undesignated payments for energy in their rent. Some variation in the count of households, particularly those containing renters or boarders, may result from the difference in definitions.
- The Current Population Survey Annual Social and Economic Supplement (CPS ASEC), conducted by the Bureau of the Census, provides, at national and regional levels, data on total household income as a specific dollar amount. CPS's larger sample size and method of collecting income data result in more accurate income data than RECS income data. Therefore, the 2017 CPS ASEC is used to develop estimates of the number of low income households. In addition, mean income statistics from the CPS ASEC are used in the calculation of group energy burden for this report.<sup>21</sup>
- Households were classified in the 2009 RECS as eligible or ineligible for LIHEAP based on whether their income was above or below the maximum statutory income eligibility criteria (the greater of 150 percent of HHS Poverty Guidelines or 60 percent of the state median income). These estimates do not include households whose incomes may have exceeded the statutory income

---

<sup>20</sup> Information about the quality of RECS data is available from the EIA website: *RECS Methodology*, Energy Information Administration, <http://www.eia.gov/consumption/residential/data/2009/index.cfm?view=methodology>.

<sup>21</sup> Note that household-level energy and income data from RECS are used to calculate mean and median individual energy burden.

standards but who received LIHEAP benefits because they (1) were categorically eligible for LIHEAP under section 8624 (b)(2)(A) of the LIHEAP statute; (2) became income-ineligible for LIHEAP at the time of the survey; or (3) were deemed eligible for LIHEAP based on incorrectly-reported income. However, the tabulations of LIHEAP households also include survey respondents who were identified as LIHEAP recipients from state LIHEAP administrative data but who reported incomes higher than the maximum statutory income in the RECS survey.

## **Average home energy consumption and expenditures**

Average heating and cooling consumption and expenditure estimates for FY 2017 were calculated at the national level for low income households (defined in this report as households with income at or below 150 percent of poverty guidelines) of LIHEAP recipient households verified in the 2009 RECS. The heating and cooling estimates were updated for each 2009 RECS sample case using FY 2017 heating degree days, cooling degree days, and price inflators applied to the original expenditure data, as well as the multiple regression formula developed from the 2009 RECS. Home energy consumption and expenditure data were developed by aggregating and averaging home heating and cooling estimates for the sample cases that represented low income households and LIHEAP recipient households.

## **Energy burden**

Energy burden is an important statistic for policymakers who are considering the need for energy assistance. Energy burden can be defined broadly as the burden placed on household incomes by the cost of residential energy. However, there are different ways to compute energy burden and different interpretations of the energy burden statistics. The purpose of this section is to examine alternative energy burden statistics and discuss the interpretation of each.<sup>22</sup>

Different “measures of central tendency” can be used to describe energy burden. The most commonly used measures are the mean and the median. As previously noted, the mean or average is computed as the sum of all values divided by the number of values. The median is computed as the value that is at the center of the distribution of values (i.e., 50 percent of the values are greater than the median and 50 percent are less).

### **Computational procedures**

There are two ways to compute mean energy burden for households.<sup>23</sup> The first is the “mean individual” approach, and the second is the “mean group” approach. While these approaches appear to be similar, they give quite different values.

Using the “mean individual burden” approach, energy burden is computed as follows.

1. First, the ratio of energy expenditures to annual income for each household in a specified population is computed
2. Then, the mean of these energy burden ratios is computed for the population.<sup>24</sup> For example, consider the situation where there are four households with energy burdens of 4, 5, 7, and 8 percent

---

<sup>22</sup> More detailed information is available in the Division of Energy Assistance's (DEA's) technical report, *Characterizing the Impact of Energy Expenditures on Low Income Households: An Analysis of Alternative Energy Burden Statistics*, (November, 1994).

<sup>23</sup> The mean is the sum of all values divided by the number of values. The mean is also referred to as the average.

<sup>24</sup> For some households, residential energy expenditures appear to exceed income. Elderly households living on their savings are an example of such households. In calculating mean individual burden, the energy burden figures for such households have been limited to 100 percent.

3. The mean of these energy burdens is calculated by adding the percentages (24 percentage points) and dividing by the number of households (four households), resulting in a mean individual burden of 6 percent.

Using the “mean group burden” approach, energy burden is computed as follows.

1. First, total annual energy expenditures for households and total annual income for households in a specified population are computed
2. Then, the ratio of total energy expenditures to total income is computed for the specified population. For example, consider the situation where a group consists of four households that have a total income of \$100,000 and a total energy bill of \$4,000
3. Dividing the \$4,000 in total energy bills by \$100,000 in total income results in a mean group burden of 4 percent.

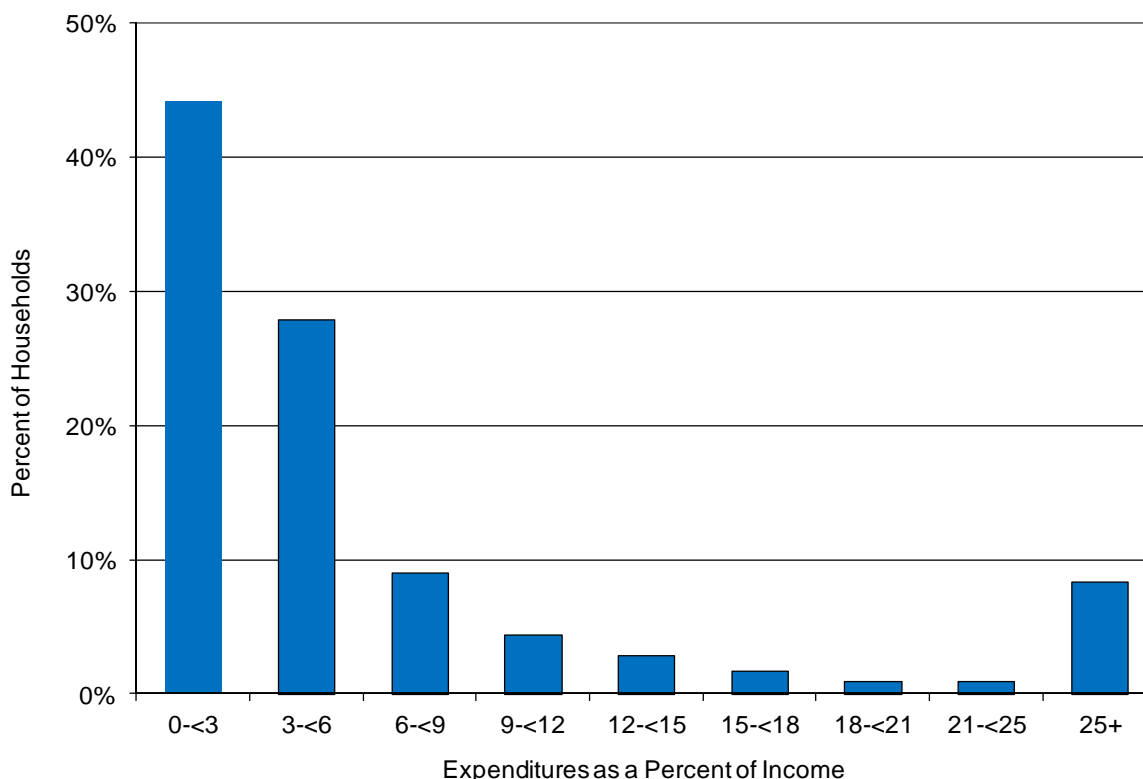

According to the 2009 RECS, the mean residential energy burden for all LIHEAP federally eligible households, in 2009, using the first approach was 18.7 percent and using the second approach was 9.6 percent. The disparity between the two statistics is because the lowest income households spend a greater share of their income on residential energy than do higher income households.<sup>25</sup> If the relationship between income and residential energy expenditures is linear (i.e., a 10 percent increase in income is associated with a 10 percent increase in residential energy expenditures), the two statistics would be equal. However, since a number of low income households spend a large share of their income on energy, the relationship between income and residential energy expenditures is not linear (i.e., a 10 percent increase in income is associated with a considerably smaller increase in energy expenditures). Therefore, there is a substantial difference between the two statistics.

In the discussion of computational procedures, the “mean individual burden” was examined. It is also possible to look at the “median individual burden.” As noted above for LIHEAP income eligible households, the mean residential energy burden computed as the “mean individual burden” was 18.7 percent. The median of the distribution of residential energy burdens from the 2009 RECS survey was 9.2 percent. The disparity between these two statistics is the result of the skewed distribution of energy burden ratios. Figure A-1 demonstrates a skewed distribution of LIHEAP income eligible households by home energy burden.

---

<sup>25</sup> For example, 2009 RECS households with incomes of \$10,000 or less had average residential energy expenditures of \$1,556, while those with incomes between \$20,000 - \$35,000 had average residential energy expenditures of \$1,714. Thus, households which had more than twice as much income spent only 10 percent more on energy.

**Figure A-1. Distribution of LIHEAP income eligible households by home energy burden, 2009**

### Data files

The data files used to make estimates of energy burden also have some impact on the statistic. The RECS data file is the only reliable source of national information on energy expenditures. However, the income reported on the RECS is known to be deficient in several ways. First, it is generally true that income is underreported on household surveys. Second, the RECS collects income data less precisely through the use of income intervals. Finally, the CPS ASEC collects income more precisely by asking a series of detailed questions on income than the RECS does and also has a larger sample size than the RECS.

The RECS, which categorizes more households as income eligible for LIHEAP than the CPS ASEC, thus categorizes too many households as income eligible for LIHEAP. Based on the 2009 RECS, in calendar year 2009, 39.7 million households were estimated to be LIHEAP income eligible households. Based on the 2010 CPS ASEC, the estimate of LIHEAP income eligible households for calendar year 2009 was 37.1 million households. Since some households that were not LIHEAP income eligible were categorized by RECS as LIHEAP income eligible, the RECS overestimated the average energy expenditures for LIHEAP income eligible households.<sup>26</sup>

### Data interpretations

The statistic used to describe energy burden depends on the question being asked. Each statistic offers some data on energy burden while not telling the whole story by itself.

<sup>26</sup> The estimates of average energy burden may be overstated since RECS, like other surveys, understates income. Comparisons between the estimates of the number of LIHEAP income eligible households from the 1990 RECS and the March 1991 CPS suggest that the probable range of the overestimate in mean group energy burden is from 5-10 percent.

The key difference between “mean individual burden” and “mean group burden” is that the first statistic focuses on the experience of individual households and the second on the experience of a group of households. The “mean individual burden” furnishes more information on how individual households are affected by energy burden (i.e., it computes a mean by using each household’s burden). The “mean group burden” furnishes more information on group burden (i.e., it computes the share of all income earned by LIHEAP income eligible households that goes to pay for energy). Both statistics are useful, though the individual burden statistic puts more emphasis on the experience of individual households, and the group burden puts more emphasis on the share of group income that is used for energy.

The key difference between the “mean individual burden” and the “median individual burden” is that the first statistic furnishes information on all LIHEAP income eligible households at the expense of overstating what is happening to the “average” LIHEAP income eligible household. The second statistic furnishes information on the “average” LIHEAP income eligible household at the expense of disregarding what is happening to households at either end of the distribution.

The best way to furnish information on energy burden is to use all available statistics. For example, it would be informative to show the “mean individual burden,” the “median individual burden,” and the “distribution of individual energy burdens,” for all LIHEAP income eligible households, to indicate how individual households are affected by energy costs. In addition, it would be useful to show the “mean group burden” to indicate what share of income is going to pay energy bills for the group as a whole.

However, when doing an analysis of energy burden among several groups of households, it is very difficult to present the entire spectrum of available statistics. Thus, we usually limit the analysis to a comparison of one statistic between groups. In general, if only one statistic is used, either the “mean individual burden” or the “mean group burden” is preferred, since a mean is a more complete statistic than is a median. The choice between the two means is dictated by which of the following types of analysis is being conducted.

- If funding levels are being examined, the group burden is probably more useful. This statistic furnishes information on the size of the energy bill of LIHEAP income eligible households and the portion of income for this group that is spent on energy. Using this statistic allows direct examination of the relationship between the total energy bill and total LIHEAP funding.
- If targeting decisions are being examined, the mean or median individual burden is probably more useful. These statistics furnish information on the distribution of burdens among households in a group. Using these statistics helps to target those groups where a significant number of households have high energy burdens.

All three energy burden statistics are presented in this report’s figures to fully inform the reader.

## **Projecting energy consumption and expenditures**

Projections were developed using microsimulation techniques that adjusted consumption and energy expenditures for changes in weather and prices. Consumption amounts for each household were adjusted for changes in heating and cooling degree days. Projected expenditures for each household were estimated as a function of projected consumption changes and actual changes in fuel prices. In order to make these projections, it was assumed that households did not change their energy use behavior (that is, their tendency to seek a specific indoor temperature) as a result of weather, price, or other changes.

Consumption projections utilized end use consumption estimates that were developed with the 2009 RECS data. These estimates were based on models for each fuel, using households that had actual (not imputed) consumption records for the fuel. The models used nonlinear estimation techniques to estimate parameters

that described the relationship of consumption to end uses, housing characteristics, weather, and demographics.

To develop consumption projections, heating and cooling end use estimates for Calendar Year 2009 were adjusted for weather differences between 2009 and Fiscal Year 2017. The following equation was applied to each household in the microsimulation data file.

$$\begin{aligned} \text{FY 2017 Projected Btus} = & (\text{2009 estimated heat use} * \text{HDD change}) + \\ & (\text{2009 estimated cooling use} * \text{CDD change}) + \\ & (\text{2009 estimated water heat use} + \text{2009 estimated appliance use}) \end{aligned}$$

Expenditure projections were a function of projected changes in consumption and actual changes in prices. The following equations were used.

$$\text{Preliminary Expenditures} = \text{2009 Expenditures} * (\text{FY 2017 Projected Usage} / \text{2009 Actual Usage})$$

$$\text{Final Expenditures} = \text{Preliminary Expenditures} * \text{Price Change}^{27}$$

Table A-1 shows the national price factors that were used. The price factors show the actual change in the average price of a fuel from calendar year 2009 to FY 2017. For example, electricity prices increased by about 11.5 percent from 2009 to FY 2017.

**Table A-1. National price factors for FY 2017**

Fuel	Price Factors for FY 2017 Projections
Electricity	1.1154
Natural gas	0.9014
Fuel oil / kerosene	0.9508
Liquefied petroleum gas (LPG)	1.0175

Expenditure data were adjusted using national price factors for FY 2017. Earlier *Notebooks* used state-level price factor data. For FY 1993/1994, state-level data did not vary much from the national average for electricity and natural gas. For electricity, price changes varied between 0.3 percent and 1.2 percent; the national average was 0.8 percent. For natural gas, price changes varied between 1.7 percent and 2.8 percent; the national average was 2 percent. Expenditure projections using national price data do not appear to be significantly different from those obtained using state-level price data.

<sup>27</sup> Price factors were developed using price data obtained from the Energy Information Administration for electricity, natural gas, and LPG, and the BLS Consumer Price Index for fuel oil. Consumption data were obtained from the Energy Information Administration for all fuels. Electricity price data used for calculating price factors are from the *Monthly Energy Review*, January 2018, and electricity consumption data is from the *Electric Power Monthly*, January 2018. Natural gas price and consumption data used for calculating price factors are from the *Monthly Energy Review*, January 2018. Fuel oil/kerosene price data for calculating prices factors are from the U.S. City Average, Fuel Oil #2, Consumer Price Index of the Bureau of Labor Statistics, Series ID APU000072511. LPG price data were obtained from the Energy Information Administration website (<http://www.eia.doe.gov>). Fuel oil/kerosene and LPG consumption data are from the *Monthly Energy Review*, January 2018.
